CLINICAL PRACTICE

Crossed renal ectopia

P. Bordei[1], I. Bulbuc[1], A.C. Rusali[1], C.R. Jecan[2,3], V. Ardeleanu[1,4,5,6]

Abstract: *The case of 73 years - old male patient with inferior crossed renal ectopia diagnosed upon imaging workup using a GE LightSpeed 16 Slice CT, with urothelial carcinoma, at the level of the left kidney, nephrolithiasis and thrombosed aneurysm at the level of the origin of right common iliac artery. The upper lobe of the right kidney fused with the lower lobe of the left kidney, on the left side of the midline. There were 6 renal arteries (4 on the left and 2 on the right) originating from the left side of the abdominal aorta, at the level of the termination of the abdominal aorta, the left common iliac artery and the right internal iliac artery. The patient presented with 6 renal veins (3 on the left and 3 on the right) that drained anteriorly on the left side of the inferior vena cava into the left common iliac vein and into the right internal iliac vein.*

Keywords: *crossed renal ectopia; arteries – veins*

INTRODUCTION

Crossed ectopic kidney (CFE) is an anomaly within the fused kidneys (FKs) group of malformations, consisting of the fusing of the upper pole of one kidney with the opposite lower pole of the other kidney traversing the midline, with a reversed L-shaped view. [1] describes 6 types of fused kidneys (FKs). [2], quoting Sousa Escandon and Aguilar Tubet, mentions that the first case of crossed renal ectopia was described by Pamarolus in 1654 and the classification of fused kidneys was done in 1957 by McDonalds and McClellan. According to [3], most frequently, the left kidney is the one fusing on the right part, aspect met in the case described by [1]. In our case, as well as in the first two cases described by [4] and in the case described by [5], it was the right kidney that traversed the midline in order to fuse with the left kidney. Numerical variation are frequently met in crossed fused ectopia of the renal veins, comporting 1 to 6 arteries originating from the aorta or the iliac veins (common and internal), and one or more veins that terminate into the inferior vena cava or in the iliac veins (common or internal). The ureters usually do not present variants or anomalies, being just one for each kidney. The renal hilum is anterior or anteromedial. Frequently, crossed fused ectopia is asymptomatic [2, 3, 5, 6] and incidentally discovered during a consult for different other medical reasons, although cases of crossed fused ectopia may present a pathology associated with congenital malformations. As associated pathologies, we have : hematuria, dysuria, urinary tract infections, renal failure, nephrolithiasis, obstruction of the ureteropyelic junction, hydronephrosis, urinary stasis, ectopic ureterocele, urothelial carcinoma [2, 3, 5, 6, 7]. As for congenital malformations, we may encounter the following: cardiac malformation, skeletal-muscle malformation, genital malformations, gastrointestinal malformation [3, 6, 7, 8, 9]. The case presented in our review was diagnosed with urothelial carcinoma of the left kidney, nephrolithiasis and thrombosed aneurysm at the level of the origin of right common iliac artery.

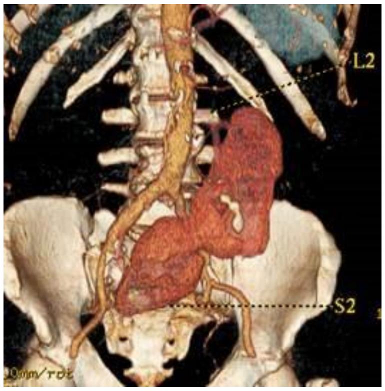
CASE STUDY

73-year old male patient, admitted at the Emergency Clinical County Hospital “Sf. Andrei” in Constanta, diagnosed with urothelial carcinoma of the left kidney, renal lithiasis and thrombosed aneurysm at the level of the origin of right common iliac artery. After the CT scan that was performed using GE LightSpeed 16 Slice CT, the patient was diagnosed with crossed renal ectopia. The right kidney crossed the midline – its upper pole fused with the lower pole of the left kidney, forming a 129,4° angle, showing a reversed L-shape aspect. The diagnosis of inferior crossed renal ectopia – type D was made, according to the classification of [1].

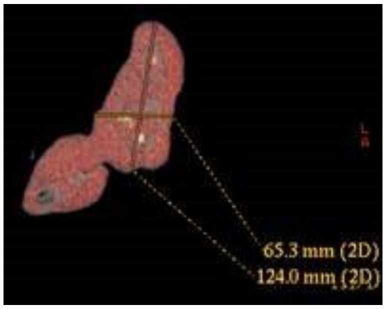
The left kidney was located vertically in the upper part and presented with the upper pole laterally to the costal processes of the L2 vertebra, covering the inferior top of the 12th rib. Its inferior pole reached the pelvis, at the level of inferior half of the S1 vertebra, at the level of sacral ala and the upper medial of the left iliac fossa. The renal isthmus, slightly oblique-inferior to the right, was located above the superior margin of the L5 vertebra and at the level of the L5 – S1 intervertebral disk and at the level of the left lateral part of the S1 vertebral body, at the level of the sacral ala. The inferior pole of the left kidney was positioned anteriorly to the sacral ala and also anteriorly to the upper medial part of the left iliac fossa. The left renal hilum was positioned anteriorly. The right kidney was horizontal (slightly oblique-lateroinferior to the right) with its superior pole corresponding to the inferolateral part of the L5 vertebral body, to the right lateral part of the L5 – S1 intervertebral disk and to the left sacral media ala, and also corresponding to the anterolateral sides of the sacral S1 – S2 vertebras. Its inferior pole overpassed the midline of the sacrum corresponding to the right lateral side of the S3 vertebra, above the anterior third sacral hole (Figure 1). The right hilum was positioned anteroinferiorly.

Figure 1: Our case of CFE in relation with vertebral column



The complex of the 2 kidneys had a longitudinal diameter of 190.6mm, a transverse diameter of 113.8mm and with a volume of 295,788 cm^3. The left kidney (Figure 2) had a bipolar diameter of 122.9mm, a transverse diameter of 65.3mm and an anteroposterior diameter of 36.5mm, with a parenchymal thickness of 20mm and a volume of 160 cm^3.

Figure 2: Left kidney diameters



The renal isthmus (Figures 3, 4) had an anteroposterior diameter of 18.1mm, a length of 31 mm, located next to the L4 – L5 intervertebral disk, 30 mm laterally to the midline.

Figure 3: Isthmus antero-posterior diameter (18.1 mm)

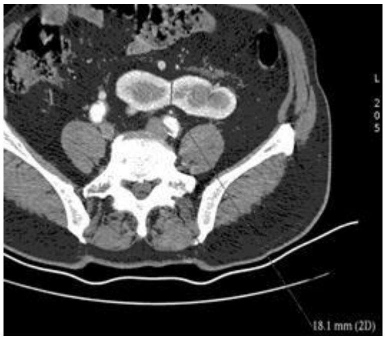


Figure 4: Isthmus lenght (30.6 mm)

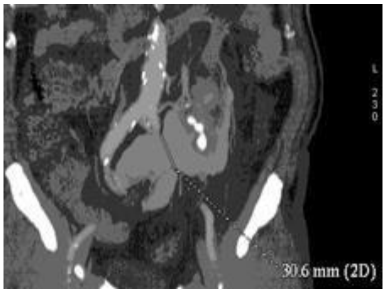
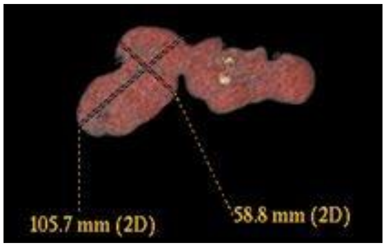


The right kidney (Figure 5) had a bipolar diameter of 105.7 mm, a transverse diameter of 58.8 mm, an anteroposterior diameter of 35.8 mm, with a parenchymal thickness of 20.3 mm and a volume of 136,295 cm^3.

The right ureter had a diameter of 6.0 mm and the left ureter presented with a diameter of 5.0 mm.

The 6 renal arteries of the cross fused ectopia (CFE) were positioned one under the other, originating at the level of the abdominal aorta and at the level of the internal and common iliac arteries, each artery with its own vascularization territory.

Figure 5: Right kidney diameters



The first renal artery originated on the left side of the aorta, approximately 19mm inferiorly to the origin of the superior mesenteric artery, at the inferior 1/3 of the L1 vertebral body, with a diameter of 1.7 mm that penetrated the upper pole of the left kidney giving birth to a branch the descended anteriorly to the bassinet.

The second renal artery also originated from the left side of the aorta, approximately 55mm inferiorly to the first renal artery, next to the right upper part of the L3 vertebra, with a diameter of 4.3 mm penetrating the renal sinus from behind the bassinet of the left kidney.

The third renal artery originated at the level of the aortic termination, next to the L4 vertebral body, approximately 40 mm inferiorly to the second renal artery, with a diameter of 4.6 mm. It bifurcated into an anterior branch penetrating the renal sinus behind the bassinet and into a posterior branch penetrating the renal parenchyma of the inferior pole issuing a branch that penetrated the renal isthmus and branches for both renal poles.

The fourth artery originated in the left common iliac artery, approximately 60 mm from the bifurcation of the aorta, with a diameter of 2.6 mm. The artery bypasses the lower left pole of the kidney, penetrating the renal sinus anterior to the bassinet flowing into the inferior mesorenal.

The fifth renal artery originated in the right internal iliac artery, at the level of its origin, approximately 62mm from the bifurcation of the aorta, with a diameter of 6.8mm; it penetrated in the right renal sinus where it bifurcated into a prepyelic and retropyelic branches.

The sixth renal artery originated in the posterior trunk of the right internal iliac artery, approximately 62 mm inferiorly to the fifth renal artery, with a diameter of 2.2 mm, perforating the renal parenchyma next to the left inferior kidney.

The left testicular artery originated from the left side of the abdominal aorta, 28 mm under the first renal artery, next to the middle of the L2 vertebral body, with a diameter of 1.7mm and in its ascending route passing behind the left bassinet, issuing a branch for the tumor formation.

There were 6 renal veins (Figures 6, 7, 8), 3 veins for each kidney – for the left kidney we had V1, V2 and V4 and for the right kidney, we had V3, V5 and V6.

Figure 6: CFE 6 renal arteries (R1, R2, R3, R4, R5, R6) and vascular territories

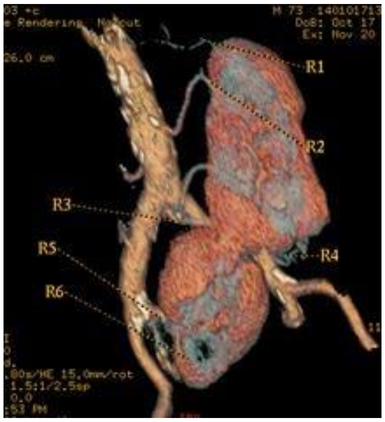


Figure 7: CFE 6 renal veins (V1, V2, V3, V4, V5, V6)

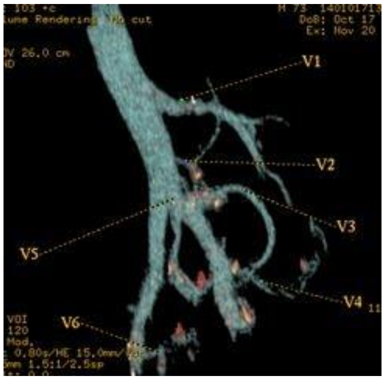

Figure 8: CFE veins and renal drainage territories

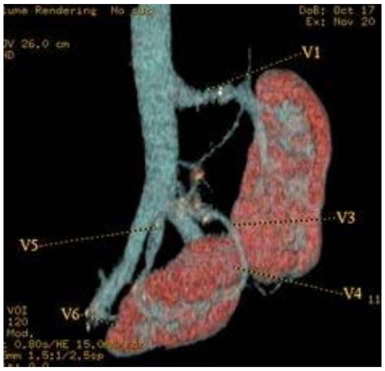

The first renal vein ended into the left side of the inferior vena cava, next to the L2 vertebra, it drained the left kidney, with a retropyelic and retroaortic trajectory and with a diameter of 9.3 mm.

The second renal vein formed by the fusing of an anastomotic branch with the first renal vein with a left lumbar branch, also ending into the left side of the inferior vena cava, next to the L3 vertebra, with a retroaortic trajectory, draining the left kidney and having a diameter of 4.8 mm.

The third renal vein originated from the right renal sinus anterior to the bassinet (also draining the upper pole), ending into the left common iliac vein, 19 mm from the formation of the inferior vena cava, with a diameter of 8.7 mm, draining the right kidney.

The fourth renal vein originated from the left renal sinus next to the inferior pole, accompaning the fourth renal artery, ending into the left common iliac vein, approximately 68 mm from the formation of the inferior vena cava, with a diameter of 5.4 mm.

The fifth renal vein originated from the renal sinus on the posterior side of the right bassinet along with the fifth renal artery was bypassing anteriorly the right common iliac artery, ending on the anterior side of the inferior vena cava, approximately 10 mm above the IVC origin and approximately 22 mm inferiorly to the second renal vein, with a diameter of 8.3 mm.

The sixth renal vein originated from the right inferior pole along with the sixth renal artery, ending in the right internal iliac vein at 33 mm inferiorly to the formation of the right common iliac vein, with a diameter of 5.2 mm.

DISCUSSION

Within the fused kidneys (FKs) group of malformations, the most frequently met is the horseshoe kidney (HK), the crossed fused ectopia (CFE) being the second anomaly in terms of frequency. The horseshoe kidney has a bigger rate of incidence: 1/400 cases according to Lawsley, Eisendrath, Bauer (quoted by 10), 1/600 according to Moore, or 1/1,200 according to Rubin (both quoted by [4]). According to [7], CFE is a rare anomaly of the kidneys, with a prevalence rate of 1/1000 – 1/7500 of cases (Wilmer, Abeshouse, quoted by 10), although a renal anomaly, according to [3] and Bauer (quoted by [7]) incidence rates of 1/300 – 1/7500 of cases. [10] considers the ratio between the frequency of CFE/HK is of 1/7.7. CFE is most frequent in male cases, i.e. double the cases in relation to female cases [9], Bauer (quoted by [7]), 3/1 Boyan (quoted by [5]) or 2.3/1 according to Muttarak (quoted by [5]). [2] describes 3 cases of CFE, 2 of which are female cases and 1 male case.

[4] describes 2 cases of CFE: in one case he finds 6 right renal arteries (2 arteries originating from the lateral side of the aorta and were destined to the left kidney; 1 artery originating from the posterior side of the aorta, vascularizing the isthmus and the left inferior kidney; 1 artery originating at the level of the bifurcation of the aorta that penetrated the left kidney on the posterior side and issued a voluminous branch for the right kidney; the right kidney was vascularized by 2 arteries – one originating on the anterolateral side of the aorta and the other originating from the right common iliac artery). In this case, he finds only 3 renal veins (2 right renal veins and 1 left renal vein). In the second case, he also finds 6 renal arteries: 2 left renal arteries originating on the lateral side of the aorta and 4 right renal arteries - 3 originating on the lateral side of the aorta and one artery originating at the level of the terminal bifurcation of the aorta. In this case, he finds only 2 renal veins – right and left.

[5] describes the case of a CFE that presented 4 renal arteries – 1 artery for the superior renal parenchyma (left kidney) and 3 renal arteries for the inferior renal parenchyma (right kidney). De venous drain was composed of 2 renal veins.

According to Papin, quoted by [7], fused renal anomalies may present with 2 renal arteries (in 20% of the cases), 3-5 renal arteries (in 66% of the cases) and more than 5 renal arteries (in 14% of the cases).

[3] quoting Bauer and bailey, considers that the total number of the arteries for a crossed fused ectopic kidney varies from 1 to most frequently met cases ranging from 2 to 4 arteries; he discovered 3 renal arteries for the left kidney and 1 renal artery for the right kidney.

[6] describes a case of CFE that presented 2 renal arteries originating in the common iliac arteries.

[9] describes one single case presented with only 2 renal arteries (originating on the sides of the aorta), the right renal artery having a precaval trajectory and 2 renal veins – the left renal vein with a retroaortic trajectory.

The origin of the CFE arteries varies, usually the main arteries or in the case where there are only 2 renal arteries originating in the abdominal aorta. [6] finds the origin of the 2 renal arteries in the common iliac arteries.

We found that out of the 6 renal arteries, 2 renal arteries (R1 and R2) originated on the left side of the abdominal aorta, one renal artery originating at the level of the terminal ramification of the aorta (R3) and into the left internal iliac artery (R4), the last 2 arteries originating in the right internal iliac artery – 1 at the level of the unique trunk of the artery (R5) and the other at the level of the posterior trunk of the right internal iliac artery (R5).

[34] finds that most frequently the origin of the CFE arteries is at the level of the abdominal aorta (lateral right side or left side, posterior side and aortic bifurcation), considering the origin of the artery at the level of the right common iliac artery.

In the case of [5], he finds the origin of the 4 renal arteries only at the level of the lateral sides of the aorta – on the right side, 1 artery and on the left side, 3 arteries.

According to [3] the origin of the fused ectopic kidney is at the level of the superior abdominal aorta (in 25% of the cases), whereas for the rest of the cases, he considers the origin at the level of the inferior aorta and the iliac arteries.

The 6 arteries penetrated the kidney at its superior pole (R1), at the level of the renal hilum (R2, R4 and R5), or at the level of the inferior pole of the kidney (R6). R3 terminated into a bifurcation that issued a hilar branch and another branch that inserted in the kidney through its inferior pole. R2 penetrated the hilum posteriorly to the bassinet whereas R4 anteriorly to the bassinet and R5 issued one prepyelic branch and another retropyelic branch.

In two of his cases, [4] finds the CFE arteries penetrating the kidneys about the same levels as ours and he also describes a renal artery for the left kidney that bifurcated into one hilar branch and into an isthmic branch, whereas for the right kidney he finds 2 renal arteries that penetrated the kidney through its anterior side, respectively at the level of its posterior side.

The most voluminous of the arteries was the fifth renal artery that vascularized the right kidney and the less voluminous artery was the sixth renal artery also destined to the right kidney.

There was no renal artery for the renal isthmus. It receives a branch through an artery destined to the inferior pole of the left kidney or through an artery destined to the right kidney.

Out of the 6 renal veins of the CFE, 3 of them terminated in the inferior vena cava, 2 in the left common iliac vein and 1 in the right internal iliac vein. The veins of the left kidney left the kidney through the upper pole (V1) and through the renal hilum (V2 and V4) whereas the veins of the right kidney left the kidney through the renal hilum (V3 and V5) and through the lower pole of the kidney (V6). Out of the veins of the right kidney, the first 2 renal veins had a posterior trajectory to the bassinet, presenting also with a retroaortic trajectory, and out of the veins of the right kidney, the fifth renal vein had a posterior trajectory to the bassinet. The veins of the left kidney terminated on the left side of the inferior vena cava (V1 and V2) and into the left common iliac vein, and the veins of the right kidney terminated into the anterior side of the inferior vena cava (V5) into the left common iliac vein (V4) and in the right internal iliac vein (V6). The first renal vein (V1) was the most voluminous one and belonged to the left kidney, and the less voluminous one was the second vein and originated also from the left kidney. There was no vein to serve exclusively the renal isthmus. Out of the 3 veins of the left kidney only the renal vein had a retroaortic trajectory.

In one of the cases [4] described, he met 3 renal veins: 2 right renal veins – one collecting the blood at the level of the left pole of the left kidney and from the level of the isthmus and flew into the left internal iliac vein, and the other collecting the blood of the upper part of the isthmus ending in the inferior vena cava, above its termination into the cava of the left renal vein. The left renal vein was normally positioned but it received an anastomosis from the left common iliac vein. The other case of CFE of [4] presented a normal left renal vein and 2 right renal veins: one originated at the level of the left pole of the kidney and terminated into the inferior vena cava, 2 cm under the termination of the left renal vein and the left pole of the right kidney with the isthmus presented a vena that terminated in the left iliac vein.

In the case described by [5] there were only 2 renal veins: the upper renal parenchyma was vascularized by a vein that terminated in the left side of the inferior vena cava and the lower renal parenchyma was drained by the second renal vein that terminated also in the left side of the inferior vena cava.

CONCLUSIONS

The case we presented is special due to its uniqueness, as we have not found a similar case of crossed renal ectopia presented with 6 renal arteries (4 left and 2 right) and 6 renal veins (3 left and 3 right) in the specialist literature.

There was no artery – vein correspondence in all 6 cases, such a correspondence was met only at the level of the pole vessels and there was only one case at the level of the hilum vessels. Regarding arteries, the most voluminous was a hilum artery, whereas the veins; the most voluminous, was a superior polar one.

We consider MDCT examination to be the best method of describing vascular and uretheral abnormalities in case of crossed fused ectopia, being able to indentify also, other associated malformation, aspect noted also by [3, 5, 7].

Patients' knowledge and attitudes regarding human papillomavirus disease and the effectiveness of education in patients referred to the Dermatology Clinic of Baqiyatallah Hospital in 2020

Hamideh Molaei[1], Esmat Davoudi-Monfared[2], Fakhri Allahyari[3], Fereshte Hamedani[4], Javad H. Nejad[3]

Abstract: *Introduction: Human papillomavirus infection considers one of the leading causes of infection-related cancer worldwide. The general public's range of knowledge and understanding of human papillomavirus is low; the present study was done intending to evaluate the knowledge and attitude of patients with human papillomavirus and the effectiveness of educational intervention in those patients.*

Methods: This was a quasi-experimental study. The study population included patients with genital human papillomavirus referred to Dermatology Clinic of Baqiyatallah Hospital in 2020. The patients filled out a pre-test questionnaire. In the next step, they were trained by the treating physician about the disease, transmission ways, complications, treatment methods, and laboratory tests, and available vaccines. After that, an educational pamphlet was given to the patient to complete and review the information. Moreover, a post-test was performed in the patient's next visit. Data were analyzed using SPSS software version 22.

Results: 92 patients were included in the study. The levels of knowledge and attitude of patients were between 50 to 65% before training and training had a significant impact on improving the level of knowledge and attitude of patients ($P < 0.001$) so that the level of knowledge and attitude of patients reached above 95%. Demographic factors such as age, gender, marital status, and level of education were not related to the initial knowledge and attitude of individuals based on the statistical analysis ($P < 0.05$). However, the knowledge of married people about the complications of the disease was more than single ones ($P = 0.032$).

Conclusion: the level of knowledge about human papillomavirus and its complications, transmission ways, prevention and treatment is low, which has increased with training significantly.

Keywords: *human papillomavirus, education, knowledge, attitude*

INTRODUCTION

Human papillomavirus infection as one of the main causes of infection-related cancers worldwide also causes other diseases like genital warts and respiratory papillomatosis [1]. According to the International Agency for Research on Cancer, the high-risk genotypes of Human Papillomavirus include types 16, 18, 31, 33, 45, 52, and 58 are responsible for about 90% of anogenital positive Human Papillomavirus cancers worldwide, however, Human Papillomavirus types 6 and 11, low-risk genotypes, are responsible for 90% of genital warts [2]. Human papillomavirus, besides anogenital cancers, is responsible for some cancers of the head and neck [3]. About 80% of sexually active people become infected with human papillomavirus during their lifetime. The immune system of the body controls most of these infections within one to two years. If the infection persists, however, it can cause cellular changes that may lead to

[4] Baqiyatallah University of Medical Sciences, Tehran, Iran

certain types of cancer [4]. The overall prevalence of human papillomavirus in a global meta-analysis of women with normal cervical cytology is estimated at 10.4%, which varies by geographical area [5]. Most human papillomavirus infections do not cause a problem and the body can clear them within two years. This is recommended for specific clinical manifestations of human papillomavirus-related disease (e.g., anogenital warts, precancerous lesions, or cancers [6].

The human papillomavirus vaccine is for the prevention of this disease, which reduces the progression of cervical cancer by up to 70%, and for better effects should be administered before or shortly after sexual intercourse [4]. According to the European Center for Disease Control and Prevention, 19 European countries have started vaccinating against human papillomavirus in women, as of 2012, and ten countries have initiated initiatives in this regard [7]. The coverage of human papillomavirus vaccination programs, despite these advances, varies greatly between countries [7]. Further, the least aware groups of the infection include racial and ethnic minorities, low-income women, with low education levels and no insurance, which are at significant risk for morbidity and mortality from the disease consequences [8]. The general public has little knowledge and understanding of human papillomavirus. It seems that the stress of diagnosing human papillomavirus infection is related to the lack of understanding of human papillomavirus [9].

Researches in Western countries suggest that most women, adolescents, and young people, even those with higher education, are not much aware of Human Papillomavirus infection [10]. In Iran, there is no public education program for human papillomavirus and vaccination for the general public.

The patients who have experienced the disease play a vital role in maintaining the disease transmission chain, and raising patients' awareness of disease transmission ways. Moreover, the treatment approaches can be very effective in decreasing disease transmission. Moreover, the relationship between human papillomavirus and cervical cancer considers important information which people must be aware of which may not even be taken seriously by the medical staff [11]. A study was conducted for surveying the attitude of patients with genital warts towards their disease in patients referred to the dermatology clinic of Razi Hospital in Iran, which indicated that patients' attitudes about various dimensions of the aforementioned disease are impaired [12]. The evolution of current knowledge and attitudes about human papillomavirus in patients is vital in trying to improve it.

This study was conducted with the aim of evaluating the knowledge and attitude of patients with Human Papillomavirus, transmission ways, treatment and its complications, training of patients moreover re-evaluating the knowledge and attitude of patients.

METHODS AND MATERIAL

The present study was a quasi-experimental one. The study population was patients with genital papillomavirus referred to the skin and hair clinic of Baqiyatallah Hospital in the year 2020. The sample size was obtained according to the prevalence of 38.6% [13].

Moreover the alpha of 5%, the beta of 20% and the sample size of 92 was obtained. The inclusion criteria of the study of human genital papillomavirus affection was confirmed and the satisfaction of participating in the study was related to the age range of 14 to 65 years. The exclusion criteria of the study was dissatisfaction of continuing the study. A researcher-made questionnaire was according to the desired trainings for patients that their validity of was questioned by referring questions to five experts. The reliability of this questionnaire was calculated using SPSS and Cronbach's alpha statistical method, which was higher than 70%, so the reliability of the aforementioned study was confirmed. The patients were asked about having satisfaction participating in the study before starting the study. At first, the patients filled out a pre-test questionnaire. Then the patients were trained about human papillomavirus in two parts. First, The doctor explained the cause of the disease, transmission ways of the disease, ways of prevention and treatment of the disease moreover its complications for the patients through face-to-face training. Second, A pre-designed pamphlet was provided for the patients, which contained complete explanations of the mentioned cases. Moreover, a phone number was given to the patient to ask any probable questions. the post-test questionnaire was filled out again after one month of revisit. Patients were included in the study in the form of encoding. The patient information was confidential. The individuals in the project adhered to all Helsinki’s moral principles.

Data were analyzed using SPSS software version 22. The results were expressed as the mean ± SD for quantitative variables and as a percentage for qualitative variables. The Chi-square and McNemar tests were used.

RESULTS

In this study, 92 infected patients with human papillomavirus were assessed about the knowledge and attitude of the disease before and after training in patients referred to the skin and hair clinic of Baqiyatallah Hospital in the year 2020. Table 1 indicates the distribution of demographic variables in patients.

The factors such as age, gender, marital status, and level of education were not related to the initial knowledge and attitude of individuals based on the statistical analysis (P <0.05), although, the knowledge of married people about the complications of the disease (P = 0.032), was more than single ones (70.8% vs. 45.5%).

The level of knowledge and attitude of patients was between 50% and 65% before training. The results indicated that training had a significant impact on improving the level of knowledge and attitude of patients as it reached above 95 at all levels after training (P <0.001) (Table 2).

Table 1: Distribution of demographic variables of age, gender, marital status and literacy level in the patient

Leadership Productivity	Factor Loading	Percentage	Frequency
Age	<30	33.3%	29
	30-40	52.9%	46
	>40	13.8%	12
Gender	Female	18.4%	16
	Male	71.6%	71
Marital status	Single	25.3%	22
	Married	76.4%	65
Education level	Less than diploma	22.9%	19
	Diploma	42.2%	35
	More than diploma	34.9%	29
History of STDs	Yes	3.4%	3
	No	96.6%	85

DISCUSSION

Human papillomavirus by silencing apoptosis (program cell death) and producing the inhibitor proteins of p53 and Retinoblastoma genes (inhibitor genes of cell growth) provides the conditions for the production of cellular cancer masses [14]. The human papillomavirus is involved in 30% of oropharynx cancers, 45% to 95% of anal cancers, 60% to 65% of vaginal cancers moreover 40% to 60% of vulvar cancers [15, 16]. The incidence of uterine and cervical cancers is about seven in one hundred thousand, based on the reports of the Cancer Institute. This cancer normally occurs between the ages of 30 and 55, even though there have been numerous reports among young women recently. [17] For this purpose, the existence of sufficient knowledge about the aforementioned virus and methods of its prevention and treatment can have a significant impact on promoting public health.

The present study surveyed the basic knowledge about human papillomavirus, its prevention, and treatment among patients referred to the dermatology clinic of a reference hospital and tried to indicate that the best solution for improving patients' knowledge and attitude is training them by conducting face-to-face training using educational pamphlet moreover providing some pieces of training. The findings indicated that the level of knowledge and attitude of patients was between 50% to 65% before training which was accompanied by improvement of knowledge and attitude of clients in all of these cases using training (P<0.001).

The present study indicated that the age factor does not have any impact on the knowledge and attitude of individuals about the causative agent, transmission ways, complications of the disease, the role of vaccines in disease prevention moreover the treatment way. Another study surveyed the information of people about this disease in various age groups. The amount of people's information has increased with the increment in the range of age (up to 40 years) [18]. The aforementioned study was not in line with the present study, which could be because of the wide age range mentioned in the study.

It was indicated in the current study, that education was not associated with knowledge and attitude of people about the cause of warts, transmission ways of disease, complications, disease, vaccine role in disease prevention moreover ways of treatment. Such an issue indicates that there is not any difference in knowledge and attitude of patients with human papillomavirus, even among highly educated individuals. On the other hand, it indicates a lack of adequate information or education in the community and at the general level too.

The present study surveyed the impact of gender on attitudes toward the disease, but any difference was not seen in this case. Another study conducted in this field which indicated that the gender of individuals doesn’t have any impact on their awareness of Human Papillomavirus moreover its related factors. [19]

63% of patients were aware of the cause of genital wart before being trained. This rate reached about 98% after revision (P <0.001). A similar study was conducted by Zu et al during which it was determined that the awareness of people of human papillomavirus was 15.5% while the awareness of people was 18.9% for human papillomavirus vaccines (20). Another study, conducted on Italian students to learn about human papillomavirus and its vaccination, indicated that 60% and 70.3% of pre-school students have relative and little knowledge about these cases, respectively. [21]

Table 2: Frequency of answers to questions before and after training

Questions	Answer	Pre-test	Post-test	P value
Identifying of the cause of the disease	Right	58 (63.04٪)	90 (97.9٪)	<0.001
	Wrong	34 (36.96%)	2 (2.1٪)	
Understanding the ways of disease transmission				
Direct and indirect skin contact	Right	57 (60.8%)	91 (99.0٪)	<0.001
		35 (38.2)	1 (1.0٪)	
Virus-infected instruments	Right	57 (60.8%)	89 (96.8٪)	<0.001
	Wrong	35 (38.2)	3 (3.2٪)	
Blood and blood products transfusions	Right	57 (60.8%)	91 (99.0٪)	<0.001
	Wrong	35 (38.2)	1 (1.0٪)	
The gyms	Right	57 (60.8%)	89 (96.8٪)	<0.001
	Wrong	35 (38.2)	3 (3.2٪)	
Hairdressers	Right	50 (54.3%)	90 (97.9٪)	<0.001
	Wrong	40 (44.7)	2 (2.1٪)	
Sexual contact	Right	55 (59.8%)	91 (99.0٪)	<0.001
	Wrong	37 (40.2)	1 (1.0٪)	
Shared facilities	Right	53 (57.6%)	90 (97.9٪)	<0.001
	Wrong	39 (43.4)	2 (2.1٪)	
Disease complications and treatment				
The complications of the disease	Right	54 (58.7%)	89 (96.8%)	<0.001
	Wrong	38 (41.3)	3 (3.2%)	
The vaccine for this disease?	Right	52 (56.5%)	90 (97.9%)	<0.001
	Wrong	40 (43.5)	2 (2.1%)	
Treatment methods	Right	46 (50.0%)	91 (99.0%)	<0.001
	Wrong	46 (50.0%)	1 (1.0%)	
Identifying of prevention				
vaccination	Right	48 (52.1%)	88 (95.6%)	<0.001
	Wrong	44 (47.9%)	4 (4.3%)	
Education	Right	46 (50.0%)	89 (96.8%)	<0.001
	Wrong	46 (50.0%)	3 (3.2%)	
Boosting of immunity system	Right	49 (53.3%)	91 (99.0%)	<0.001
	Wrong	43 (46.7%)	1 (1.0%)	
Prevention by medication	Right	47 (51.1%)	90 (97.9%)	<0.001
	Wrong	45 (48.9%)	2 (2.1%)	

The knowledge of the subjects in the present study about vaccination was 52% before training which reached 95% after training. The amount of training and advertising about Vaccines in our country has been poor. The present study is designed to indicate the importance of training about vaccines while the amount of training about this vaccine in other countries is much more extensive and is being conducted with a variety of tools.

Clients were informed about the transmission ways of the disease. Various factors including direct and indirect skin contact, virus-infected equipment, blood transfusion, and blood component, gyms, hairdressers through waxing, sexual contact, and common equipment in the dormitory were examined during conducting this study. The knowledge of people was between 57-50% before training which reached 91-89% after training.

Other studies have surveyed the amount of awareness of people of transmission ways of the disease, which indicated a variety of various results [22]. A study by Joshi et al. found that 44.3% of subjects were aware of the transmission ways of the disease [18]. Moreover, it was concluded in this study that both the level and type of education of individuals have significant impacts on their awareness of the aforementioned virus as well as its vaccination and treatment.

CONCLUSIONS

The knowledge and attitude of patients with human papillomavirus disease, despite its importance, seem not to be enough. However, effective and well-planned education can have a significant impact on the knowledge and attitude of patients with this disease. Thus, it is suggested that in public education programs, the important educational points about Human Papillomavirus must be given priority.

Peer review process

We, at the Romanian Journal of Military Medicine, understand the importance of the peer review process in upholding the quality of scholarly publications. Once a manuscript is received online from the author, it passes the following stages:

1. The manuscript received is first handled by the journal management team. During this stage, the manuscript is checked for plagiarism and grammatical errors. We use different high-quality reliable software to detect plagiarized content and grammatical errors in manuscripts.

2. After successfully passing the first step, the manuscript assigns a unique code. The coded manuscripts are then forwarded to the assigned Handling Editor for the blindfolded review process.

3. Three reviewers are selected by the journal management team on given parameters. All three reviewers are provided with the template of the reviewers' report to facilitate a structured review format. Reviewers need to submit their evaluation report within 14 days.

4. Evaluation reports received from the reviewers are analyzed by the manuscript’s Handling Editor and the author is informed about the reviewers’ opinions. If any abnormalities have been found in the manuscript, the author will be asked to make the required changes and resubmit the manuscript.

5. The corrected manuscript is then resubmitted to the reviewers, to have a new decision. It is possible to have more than one round of corrections, based on the reviewers' decision.

6. The finally accepted form of the manuscript is handled by the journal editorial team for possible copyediting. Copyright form and ethical clearance letter are to be obtained from the author.

7. At any moment, the Handling Editor can decide to reject the manuscript, based on presented arguments.

8. The final decision regarding the acceptance of any manuscript is bestowed to the Executive Editor and the Editor-in-Chief.

9. Authors are then communicated about the publication of the corrected manuscript in an upcoming issue of RJMM. After issuing the doi number for the article, the author will receive a letter of acceptance.

10. This process may take a few weeks depending upon reviewers’ responses to the manuscript evaluation. The process ensures that the identity of reviewers is kept confidential and cannot be revealed to authors.

The article was received on June 23, 2020, and accepted for publishing on September 23, 2020.

Peptide nucleic acid (PNA) as a novel tool in the detection and treatment of biological threatening diseases

Mohammad S. Hashemzadeh[1]

Abstract: *Peptide Nucleic Acids (PNAs) are nanostructures similar to nucleic acid molecules (synthetic DNA/RNA analogs) wherein the negatively charged backbone (sugar-phosphate) present in DNA/RNA molecules is replaced by a backbone without polyamide or peptide charge. Later, it was found that PNAs containing both purine and pyrimidine bases form highly stable duplexes with DNA and RNA. Although it is not as stable as 2PNA/DNA triplexes containing a homopyrimidine strand, it is still more stable than DNA/DNA and/or DNA/RNA duplexes. The unique characteristics of PNAs add new aspects to these nanostructures relative to conventional analogs to make them appropriate for molecular biology studies. The most important applications include the use of these nanostructures in the detection and treatment of diseases caused by threatening biological agents using the antisense/antigen technology and as genetic regulator drugs.*

Keywords: *Peptide Nucleic Acids (PNAs), synthetic DNA analog, genetic regulator drugs, antisense-antigen technology*

INTRODUCTION

Nielsen et al. (1991) were the first who reported the synthesis of a molecule, called Peptide Nucleic Acid (PNA), as a novel, completely synthetic analog of nucleic acids, which was commercialized in 1993 [1]. PNA molecules are considered as DNA/RNA synthetic analogs where the negatively charged backbone (sugar-phosphate) present in DNA/RNA molecules is replaced by a backbone without polyamide or peptide charge [2].

Biochemically, the main backbone of PNA structure forms by repetitive units of N-(2-aminoethyl) glycine connected by peptide bonds, and different nucleobases (purine and pyrimidine) are attached to the main backbone through methyl carbonyl linkers [3]. The same peptides are also drawn as the C-terminus and N-terminus, a state corresponding to 3′ and 5′ termini in DNA [4]. These characteristics render PNA to be stable biologically, making it usable in therapeutic applications [5].

IMPORTANT CHARACTERISTICS OF PNA MOLECULES

1) PNAs have extremely high affinity, specificity, and sensitivity to interact with nucleic acids (RNA/DNA), which is 50-100 times stronger than a typical DNA/DNA or DNA/RNA hybridization.

2) They possess a very high hybridization ability.

3) The occurrence of a mismatch or single nucleotide polymorphism (SNP) in their hybridization with DNA or RNA leads to a very strong destabilizing effect in the hybrid

Corresponding author: Mohammad S. Hashemzadeh
Dr_Hashemzadeh@bmsu.ac.ir

formation, which strongly reduces the annealing temperature.

4) PNAs are very stable molecules both chemically and biologically.

- Extremely high chemical stability to temperature and pH.

- Extremely high biological stability to nuclease and protease enzymes, meaning that they are resistant to enzymatic digestion and hydrolytic processes.

5) Their hybridization with such nucleic acid molecules as DNA is independent of environmental salt concentrations.

6) They attach to DNA or RNA strands the same as common Watson-Crick attachments.

7) The formation of a triplex with DNA is possible when PNA containing two homopyrimidine oligomers interlinked by a flexible linker reacts with the DNA homopyrimidine fragment. In such a case, a PNA strand through Watson-Crick pairing and the other via Hoogsteen pairing interact with DNA, with a DNA strand extruding the triplex structure, which will have many applications in gene expression regulation.

8) They have an asymmetric, peptide-like, and uncharged structure, which is hydrophilic and water-soluble.

- Although the uncharged nature of PNA facilitates its delivery through the cell membrane, this transfer into the cell is a difficult process requires using a variety of carriers.

- The uncharged nature of PNA molecules results in their much stronger interconnection (than DNA/DNA and/or DNA/RNA) due to the lack of electrostatic deterrence with DNA and RNA molecules.

9) Tm is much higher for PNA hybrids than other hybrids (DNA/DNA and/or DNA/RNA), with Tm values of 50 and 70 °C for PNA hybrids of 10mer and 15mer, respectively.

It is noteworthy that triplex structures with DNA are better formed in acidic pH (4.5-6.5) in vitro, but the main prerequisite is the presence of PNA pyrimidine.

As mentioned above, the PNA-PNA hybrid is extremely thermostable and is independent of environmental ionic potential, such that PNA-PNA > PNA-RNA > PNA-DNA > DNA-DNA. This stability, however, is strongly affected by basic compositions in the PNA sequence, such that Purine PNA >> pyrimidine PNA; among pyrimidines, on the other hand, homopyrimidines show very high stability.

Due to the very high binding ability of PNA molecules with DNA, it is not necessary to design long PNA oligomers hence fragments of 20-25 nucleobases are appropriate [6-10].

PREPARATION AND STORAGE OF PNA SUSPENSION

PNA can be easily dissolved in 0.1% trifluoroacetic (TFA) and the prepared stock can be stored frozen for a long time [7].

PNA hybridization and the salt effect

As denoted previously, the Tm of the PNA molecule does not change significantly with changes in environmental ionic potential. As such, the Tm of a 15mer PNA duplex only decreases 5 °C with an increase in NaCl concentration from 10 mM to 1 M, but the altered concentration has a very strong effect on the Tm of DNA/DNA hybridization. As a result, PNA can serve as a very suitable probe for the identification of target sequences at low salt concentrations.

Tm drops significantly due to a mutation in the allele of a gene and the incidence of a mismatch with PNA. In mismatch detection, therefore, DNA probes are the winners in competition with PNA probes, and this hallmark can be used in the detection of allele type [8].

Advantages of PNA molecules with very stronger pairing characteristics

PNA fragments with very shorter lengths can be used as probes, with lengths of 20-25 meres for DNA probes, but those of 13-17 meres long also operate well as PNA probes.

2) This hybridization is over 100 times faster than DNA/DNA and/or DNA/RNA hybridization. For example, if DNA hybridization lasts about 3 h to overnight, PNA hybridization will last 30-45 min.

3) As mentioned above, the incidence of a mismatch in this hybridization will result in more destabilization than typical DNA/DNA duplexes. This will significantly reduce Tm, leading to a decrease in the specificity because of a reduction in the annealing temperature as well [9-13].

Some disadvantages of using PNA

1) It takes a high cost for mass production as it is produced synthetically.

2) In the PCR process, the polymerase primer cannot detect its C-terminus and only detects the 3' terminus.

3) It cannot be amplified by the cloning process [14].

SOME PROBLEMS OF PNA IN CLINICAL APPLICATIONS

1) The dose and toxicity problem

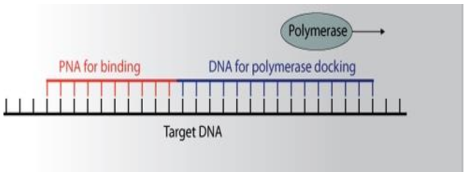
A dose that responds properly in vitro is toxic to the body (both PNA itself and the associated molecules such as cationic peptides); hence, dosimetry should inevitably be done to determine the toxicity level.

2) The delivery problem: It is difficult to deliver it into target tissue cells and has a low efficiency [15].

PCR clamping

This feature can be used in the detection of point mutations or SNPs in which an allele-specific primer competes with an SNP-containing PNA primer. If the SNP occurs in the relevant allele, PNA will win the competition (due to its higher Tm in normal conditions) and PCR will cease. If SNP does not occur, PNA will have a mismatch, Tm drops, and consequently, the primer will be the actual winner, leading to the occurrence of PCR (due to a higher Tm), which will be visible on the PCR agarose gel (Figure 1) [16].

Figure 1: The use of PNA in the PCR process



VARIOUS APPLICATIONS OF PNA MOLECULE

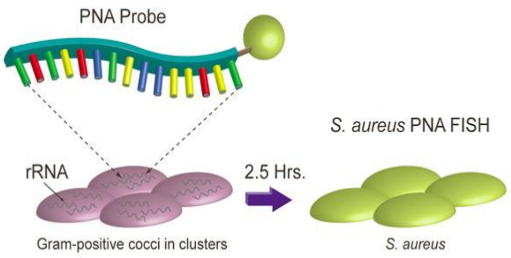
PNA molecule can be applied:

1. As a probe for the diagnosis and detection of biological threatening diseases, including:

1.1 Fluorescent In Situ Hybridization (FISH) probe

In this method, PNA labeled probes are utilized to detect certain telomeric reigns of the human chromosome or other specific sequences in various organisms. An example of this application in the detection of a conserved sequence on the rRNA of Staphylococcus aureus is depicted in Figure 2.

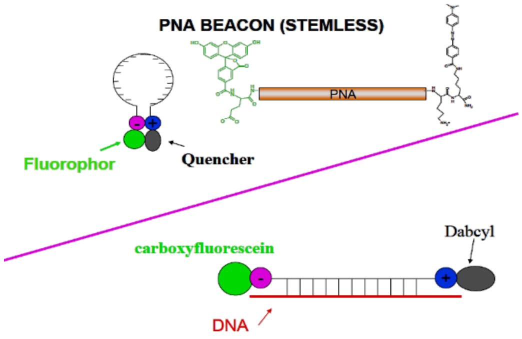
Figure 2: The use of PNA molecule as a specific probe in FISH



1.2 Detection of SNPs as described above
1.3 Light UP probe (or Q-PNA probe)

PNA is used as a probe in real-time PCR (RT-PCR) so that fluorescein and a quencher can be placed on each terminus of the molecule. A molecular beacon model of RT-PCR is shown in Figure 3.

Figure 3: The use of PNA as a probe in RT-PCR



2. As a molecular tool in functional genomics research, including:
2.1 A probe for the northern and southern blot processes
2.2 PCR Clamping
2.3 In the separation and purification of the target DNA molecule
2.4 PNA array, which can be used in the PNA-based microarray technique.

3. The use of PNA as regulator drugs, including the antisense and antigene effects and so on, is one of the most important applications of PNA that has been the focus of worldwide research [17], which is discussed further in the following.

In the antisense application, PNA is designed against cellular RNAs, and in the antigene application, PNA is designed against the gene fragment (DNA). This indicates that many genetic diseases can be treated that are caused by defects in a gene function and/or overexpression; it can also be effective in cancer treatment, which often results from disrupted gene expression. In other groups of diseases, PNA is designed against cellular RNAs, such as in AIDS, where cDNA is synthesized from cellular RNAs through the action of reverse transcriptase. If PNA can react with RNA, it will inhibit the action of this enzyme on RNA and ceases the above reaction, thereby controlling the disease [18].

GENETIC REGULATOR DRUGS

1. The antigene technology

In this application, PNA is used as a gene inhibitor that needs to form a triplex with a double-strand DNA. Based on nucleobase combinations in DNA, this PNA is designed against external gene enhancer fragments that play a key role in the onset of transcription to inhibit the transcription process by RNA polymerase. This will occur when the designed PNA is attached to the non-coding strand of the gene enhancer as it plays the role of a template. PNA can be designed against the promotor region (−10 and −35) to further inhibit the non-coding strand and is not accessible to the enzyme. PNA can also be designed against the internal gene enhancers or other internal gene sequences containing homopurine sequences and their strong hybridization with DNA results in incomplete transcription of the gene and no expression of the target gene; it can also be very effective in cancer treatment as mentioned above [19].

2. Direct activation of gene

The gene is activated in this application unlike the antigene effect aiming at inhibition of gene expression as described above. The triplex forms in such a way that will extrude the non-coding strand. PNA is designed against the coding strand concerning nucleobase combinations and will be used in many genetic diseases caused by a defect in the functional expression of a gene. The target gene, which has become part of the heterochromatin, will occasionally return to the euchromatin by the effect of PNA and become accessible to transcription enzymes [20].

3. The antisense technology

This application uses synthetic PNAs against the transcribed gene product (sense-RNA) such that the PNA oligomers are started against the Shine-Dalgarno sequence, the codon region, or the internal mRNA sequences; in the latter case, it results in the inhibition of protein elongation process by the ribosome. In most cases, antisense PNA is simultaneously designed against the Shine-Dalgarno sequence and the codon region, as these two are not much apart. In such cases, the strong PNA/RNA hybrid becomes a stable duplex and is prevented from the translation process [21].

4. Inhibition of 16S rRNA

In this case, PNA is designed against rRNAs in the ribonucleoprotein (RNP) structure, the most important of which in bacteria is the 16s as it plays a role in the attachment of ribosome to the Shine-Dalgarno sequence and inhibition of 16S rRNA, i.e. inhibition of ribosome attachment to mRNA, thereby inhibiting protein synthesis. Existing evidence indicates that PNAs designed against 16S rRNA and 23S rRNA segments play a bacteriostatic role (cessation of bacterial growth and protein synthesis). These PNAs are considered effective drugs and genetic antibiotics (instead of chemical antibiotics) [22].

5. Inhibition of microRNAs

These RNAs play a regulatory role in gene expression. A PNA oligomer can be designed to inhibit the function of a given mi-RNA in which mi-RNA, as an inhibitor of certain gene expression, is bounced out to resume the expression of such genes. This application can be utilized in many diseases caused by the aberrant presence of mi-RNAs (where they must not be present) [23].

6. Inhibition of telomerase function

A reason for cancer cell immortality can be the continuous activity of this enzyme and its re-expression due to the activity of a series of oncogenes. If the PNA fragment is designed against the RNA part of this enzyme, it inhibits the enzyme function and cures cancer [24].

7. Alternative splicing

Here, a specific PNA is designed against splicing-specific sequences in pre-mRNA to change the mRNA product and ultimately achieve target gene expression. Accordingly, PNAs can play a role as regulator drugs in the treatment of bacterial and viral infections, as well as many other diseases [25].

SOME IMPORTANT CLINICAL APPLICATIONS OF PNA

1. Cancer therapy

As described above, this application can be achieved by the suppression of telomerase. Thus, PNA can also be considered as an anti-cancer drug, or exert antisense and antigene effects on such genes as Bcl2. This begins by designing a PNA probe against the codon region, the Shine-Dalgarno sequence, or homopurine sequences on the coding DNA strand to reduce the expression level of Bcl2 and prevent cancer cells from using this mechanism for their survival [26].

2. Treatment of biological threatening diseases

Research has shown that the PNA molecule can effectively inhibit the function of reverse transcriptase that has a contribution to disease development. Indeed, this enzyme synthesizes a cDNA by the detection and transcription of template RNA. An appropriate and specific PNA oligomers can be designed to effectively improve these viral infections (27).

PNA DELIVERY STRATEGIES TO THE CELL

As denoted before, it is very difficult to deliver PNA to eukaryotic and prokaryotic cells, with low efficiency. For this reason, strategies are employed to facilitate the delivery process, some of which are described below.

1. Making some modifications in their main backbone structure

2. Pairing them with peptide delivery groups

3. Paring them with cationic peptides (lysine and arginine

residues)

4. Coupling them with some DNA oligomers

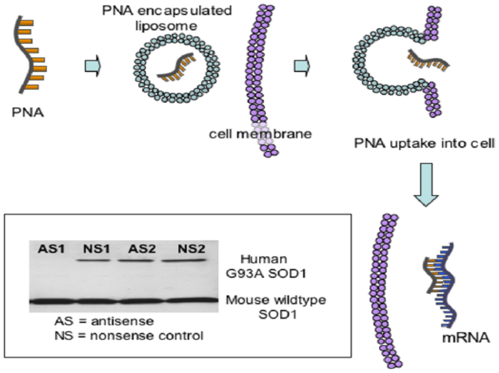
5. Coupling them with specific ligands (e.g., antibodies) linking to cell surface receptors

6. Delivery using liposomes for which typical liposomes should be used instead of cationic liposomes due to their toxicity despite higher efficiency.

7. By the use of cationic polymers

Figure 4 illustrates a schematic of the delivery of a PNA molecule using liposomes.

Figure 4: Delivery of PNA molecule to a eukaryotic cell using liposomes



PNA

RESULTS AND DISCUSSION

As noted above, the main backbone of PNA structure forms by repetitive units of N-(2-aminoethyl) glycine connected by peptide bonds. As with peptides, these are drawn by C and N terminus that correspond to the 3′ and 5′ terminus in DNA (Figure 5).

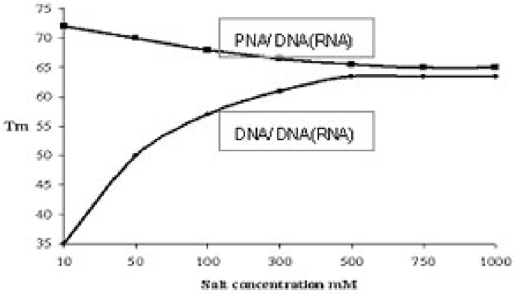
PNA

Tm changes are insignificant for PNA with fluctuations in environmental ionic potential in comparison to DNA and RNA. Thus, PNA can serve as a very appropriate probe for the detection of target sequences at different salt concentrations (Figure 6) [28].

Figure 6: Ionic and thermal changes of PNA/DNA and DNA/DNA



As mentioned above, PNA is designed against the gene fragment (DNA) and cellular RNAs in the antigene and antisense techniques, respectively (Figures 7 and 8).

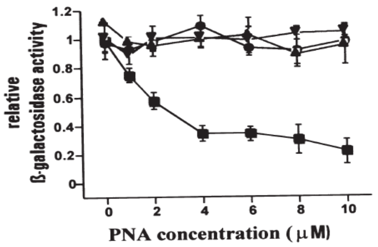
Figure 9: Changes in β-galactosidase activity with rising inhibitory PNA concentrations



Anti-β-galactosidase PNA was reported to inhibit the expression of the β-galactosidase reporter gene in E. coli AS19. As shown in Figure 9, the activity of this enzyme decreases with an increase in PNA concentrations, indicating the decreased expression of this gene by a specific PNA. Control samples are presented in the diagram (Figure 9) showing a change in the enzyme activity.

Therefore, these two critical technologies can help to effectively improve diagnostic and therapeutic goals.

CONCLUSION

Overall, it can be concluded that PNA nanostructures are currently considered by scientists to have a wide array of applications.

Accordingly, further investigations on these nanostructures will provide an effective tool to achieve the above diagnostic and therapeutic goals.

Medical and molecular biotechnology has been revolutionized with the synthesis of PNA.

Planning a hospital to respond to the COVID-19 outbreak: experience from a Romanian reference unit

Gabriela Hofer[1], Dodu G. Petrescu[1], Victor L. Purcărea[1]

Abstract: *During the COVID outbreak, many hospitals were nominated as a support hospital for the treatment of positive tested patients infected with SARS CoV-2 virus. "Dr. Nicolae Ruşdea" Pneumophtiziology Hospital Baia Mare carried out an exceptional activity compared to the previous year considering the current epidemiological context. Major changes were made in strategies, procedures and protocols. The staff had to adapt to the new epidemiological situation through dedication and devotion. In 2020, there were no COVID outbreaks within the unit, as separate compartments were made, intended to protect the medical personnel, but also to ensure the health of the patients.*

Keywords: *COVID plan, hospital, Romanian reference unit*

INTRODUCTION

"Dr. Nicolae Ruşdea" Pneumophtiziology Hospital Baia Mare is a specialized hospital providing medical services in the specialties of pneumology for adults and children. Starting with April 2020, it provides hospital care for patients tested positive for the SARS-CoV-2 virus, including intensive care. In 2020, the hospital served the entire county of Maramureș for patients tested positive for SARS-CoV-2 virus. In the intensive care department, patients from Maramureș County received health care, mainly from the country, depending on the places available at the request of the Committee for Emergency Situations. Throughout this period, the fight against pulmonary tuberculosis continued through the national control and surveillance program as well as ensuring the continuity of integrated ambulatory care services for patients with non-Covid pneumological diseases and the follow-up of post-Covid patients. Compared to the previous year, considering the current epidemiological context, which led to major changes in the way of working, procedures and protocols. In order to provide the resilience of health systems during the COVID-19 pandemic, we describe, at the hospital level, the key elements to provide the medical staff sand patients safety, including the challenges and issues to anticipate following the experience of our center

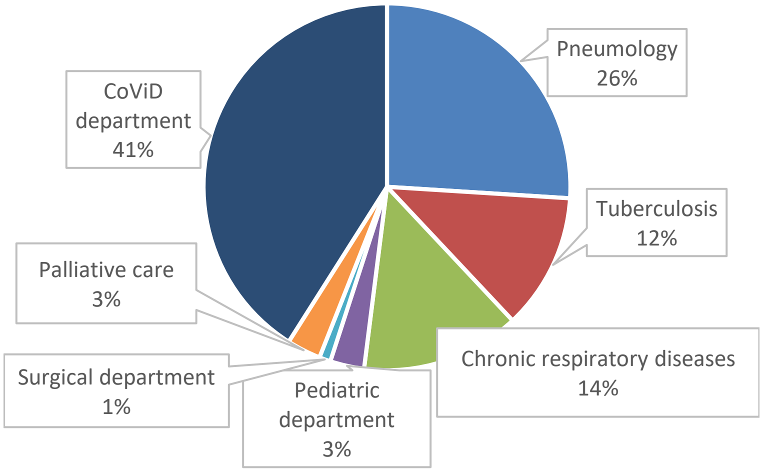
CLINICAL EXAMPLE

The aim was to establish synergies between health worker safety and patient safety policies and strategies, developing linkages between occupational health and safety, patient safety, quality improvement, infection prevention and control programmes [1]. It was necessary to review and upgrade the standards, guidelines and codes of practice in order to assure the health worker and patient safety [1]. The executive board consisting of a multidisciplinary team: general manager, epidemiologist and the technical-administrative staff, planned the separation of the hospitals' circuits in COVID and NON-COVID. During the pandemic, the hospital changed his usual structure, consisting of 2 departments of medical specialties (pneumology, intern medicine, cardiology, urology, metabolic diseases,

[1] Clinic of Obstetrics and Gynecology, Diakonie Klinikum, Schwäbisch Hall, Germany

neurology), one section of surgical specialties, one pediatric department, a department ICU (intensive care unit), blood transfusion units, palliative care and an operating room. The rest of the structure was maintained: farmacy, sterilization, medical analysis laboratory, radiology department, tuberculosis dispensary, reception desk, evaluation and medical statistics department (Figure 1).

Figure 1: Plan for new structure of the hospital to augment the health system during the pandemic.



After the State of emergency in the coronavirus pandemic, depending on the local epidemiological evolution, the hospitalizations and the scheduled surgical interventions can be resumed, as well as the activity in the outpatient clinics. Being a 4-storey Hospital, a level was created for the green zone, non-COVID, and the 2nd and 3rd floor were allocated for the COVID section - red zone, served by an elevator: at each level a separate filter for dressing and undressing the protective equipment; the 4 elevators and 6 exits of the hospital had separate destinations: a red zone entrance, one for staff, one for drugs and one for food. A special elevator for patients, one for the staff and the elevators on the opposite side of the building are used for waste and medical staff. A separate circuit was intended for the ICU section, and a separate one for the rest of the staff. In the green area, the staff was separated, depending on the section, so as not to be conglomerated by people. Radiology department: provides a separate circuit for non-COVID patients hospitalized, and a dedicated department for tuberculosis dispensaries. Also a sequential circuit for computer tomography access. The organization of the COVID departments provides a separate circuit for access to the Covid patients section with a dedicated elevator only for COVID-positive patients. The medical personnel circuit with clothing filter area, decontamination area, green area for rest and document preparation (common for COVID and ATI section). The contaminated waste had a special circuit - collection and transport on a circuit intended only for waste (all waste generated in the COVID section are considered hazardous waste). The food circuit, consisting in disposable dishes, are collected as infectious medical waste. Assistance to acute and chronic non-COVID pneumology patients was assured. When entering the hospital, all people will go through an epidemiological triage, depending on the symptoms presented, the suspicious cases will be hospitalized in special isolation areas (buffer-zones), organized at the 1st floor, to be tested by RT-PCR for SARS-CoV-2 infection (according to the recommendations of the National Institute of Public Health). Separate circuits are provided for these patients.

DISCUSSIONS

With all the circuits, red-zone and green-zone, the hardest part was teaching the staff to overcome fear, but the idea that you have some completely separate safe circuits made the staff trustful and work, and accept the new rules imposed. Moreover, having 4 training teams that teaches the use of the protective equipment, the existence of a supervisor in the first 3 months to monitor the dressing and undressing the equipment, in order to avoid mistakes. As a result, there was no outbreak in the hospital for 12 months, with only isolated cases coming from outside of the hospital.

CONCLUSIONS

The coronavirus disease (COVID-19) outbreak is a global public health problem. Medical personal is an important at-risk population that can get COVID-19 due to close contact with patients2. The healthcare reform, with subsequent amendments and additional changes, caused a new reorganization and restructuring of health units, depending on the needs, in order to ensure the isolation conditions and the functional circuits that aim at the prevention and control of the SARS-COV-2 infection3,4. The reorganization and restructuring of the health units subordinated to the local public administration authorities will be done with their consultation. The reason for these changes is mostly because of the epidemiological evolution of the SARS-COV-2 virus pandemic. In addition, there is an increased addressability of patients with pneumological problems including patients with pulmonary diseases after SARS-COV-2 infection that need recovery. Also, the need to carry out the activities of the tuberculosis prevention and control programs.

ORIGINAL ARTICLE

Post-traumatic stress disorder and cardiovascular disease

Corneliu A. Moraru[1], Elena D. Năfureanu[1,2], Adelina Proca[1,2], Iuliana Zavadovschi[1], Mariana Floria[1,2], Dragoș M. Popescu[3]

Abstract: *Posttraumatic stress disorder (PTSD) is a psychological-psychiatric state caused by exposure to stressful, traumatic events that manifests as a vivid reminiscence of them by flashbacks, nightmares, reccurent memories, emotional and physical manifestations. Cardiovascular diseases (CVD) are of interest in patients suffering from PTSD because there is an increasing body of evidence that these pathologies are linked. Hypertension, dyslipidemia, diabetes, and other cardiovascular risk factors are common in patients with PTSD and all of them increase the incidence of coronary syndromes, both chronic and acute. Posttraumatic stress disorder has a major impact on the lifestyle and health of subjects exposed to trauma or stress. Cardiovascular diseases tend to appear sooner in PTSD diagnosed patients due to a variety of reasons: poor habits, low addressability to health care systems, chronic inflammation status, changes at molecular levels, etc. Otherwise, PTSD tends to be induced by CVD, thus inclining the balance towards whis association. According with data published until now, there is a strong pathophysiologic relatonship between PTSD and some CVD; there is also outlining a vice versa relationship, from some CVD to PTSD.*

Keywords: *posttraumatic, stress, disorder, cardiovascular, disease*

INTRODUCTION

Posttraumatic stress disorder (PTSD) is a psychological-psychiatric state caused by exposure to stressful, traumatic events that manifests as a vivid reminiscence of them by flashbacks, nightmares, recurrent memories, emotional and physical manifestations.

Cardiovascular disease (CVD) is of interest in patients suffering from PTSD because there is an increasing body of evidence that these pathologies are linked.

Posttraumatic stress disorder seems to be associated to an increased risk of CVD due to its psychosocial consequences that become cardiovascular risk factors and due to its ability to cause cardiovascular structural changes and alter the neuroendocrine mechanisms involved in maintaining body functions. This disorder is mainly associated with hypertension and coronary artery disease but it can also lead to arrhythmia or stroke, with recent studies bringiging into attention the pathological link at molecular and genetic levels. The shortcomings of existing studies are that they do not report the incidence rate of each CVD after exposure to stressful events but rather tell us about the incidence rate of cardiovascular risk factors in populations suffering from PTSD (mostly military field workers, either veterans or active soldiers).This systematic review of the literature aims to bring forward the extent to which PTSD can cause damage to the cardiovascular system and to present the pathological link between PTSD and CVD as well as to present the vice-versa relationship: PTSD induced by CVD.

MATERIALS AND METHODS

We conducted the present systematic review in concordance with updated Reporting Items for Systematic Review and Meta-Analyses (PRISMA) guidelines [1]. A literature search using a prespecified MeSH combination of words (“posttraumatic stress disorder " AND "cardiovascular disease”) was performed in PubMed and Google Academic. Two essential inclusion criteria were defined and applied for retrieved citations which guided the eligibility assessment: (1) randomized controlled and non-randomized clinical trials

---

[2] Grigore T. Popa University of Medicine and Pharmacy, Iași, Romania
[3] University of Medicine and Pharmacy, Craiova, Romania

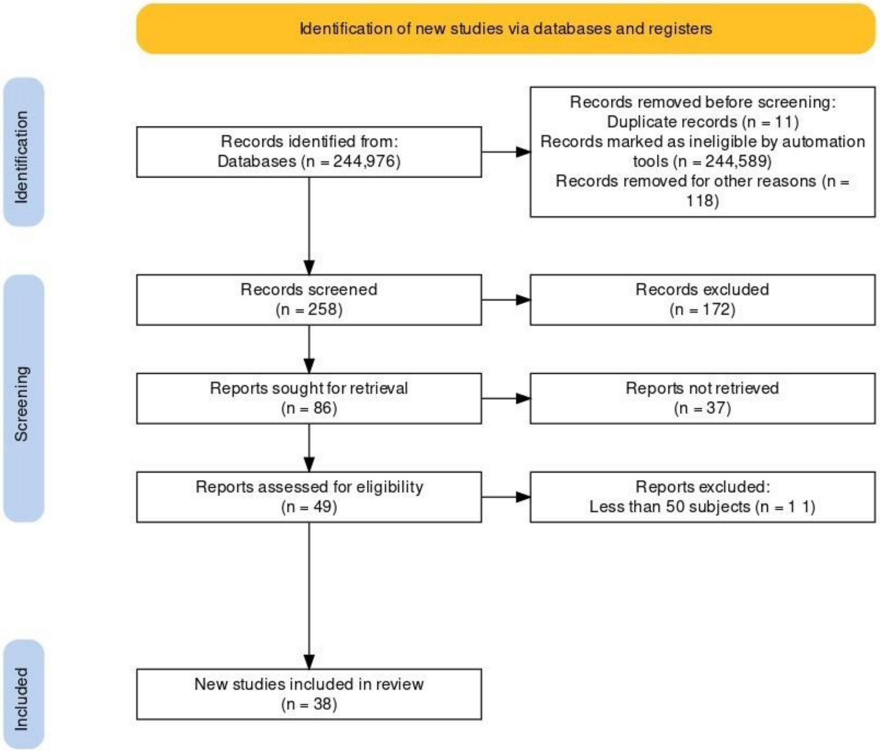
with available abstract (for PubMed) and containing ”the exact phrase” (for Google Academic); (2) studies which enrolled at least 50 patients or more (due to the high probability of not having a significant statistical power). Additionally, studies were excluded from the analysis if they met at least one of the following criteria: articles that could’t be retrieved because of access to the editorial, doubles, articles written in languages other than english, other types of literature (books, e-books, disertation thesis, article in press), studies conducted on animals and articles that have not treated the issue of our search. All studies without PTSD diagnosis defined by the Diagnostic and Statistical Manual of Mental Disorders (DSM-III), DSM-IV, DSM-5 or International Classification of Diseases (ICD-10) were excluded. We taking into consideration the reviews, systematic reviews and meta-analysis only in discussions, to avoid duplications and bias selection.

Two independent investigators decided if studies fulfilled the inclusion criteria and any disagreements were solved by discussion and consensus.

RESULTS

The flow-chart of the search process as well as complete databases search strategies were provided in Figure 1. We retrieved a total number of 244,976 articles from both databases out of which were removed 244,589 due to automation tools presented above, 11 doubles and other 118 articles that were other types of literature or whose abstract was written in other language than english, resulting in 258 articles for screening.

Figure 1: Systematic search of the literature: PRISMA flowchart



Identification of new studies via databases and registers
Identification
Records identified from: Databases (n = 244,976)
Records removed before screening: Duplicate records (n = 11) Records marked as ineligible by automation tools (n = 244,589) Records removed for other reasons (n = 118)
Screening
Records screened (n = 258)
Records excluded (n = 172)
Reports sought for retrieval (n = 86)
Reports not retrieved (n = 37)
Reports assessed for eligibility (n = 49)
Reports excluded: Less than 50 subjects (n = 1 1)
Included
New studies included in review (n = 38)

After exclusion of 172 articles (19 presenting studies conducted on animals and the rest not being of interest because they did not debate the relationship between PTSD and CVD), another 37 could not be retrieved and 11 not being taking in consideration because they used less than 50 subects in trials.

The final number of articles used in our systematic review was 38 (n=2,507,724 patients): 25 prospective (n=1,451,924 patients) and 13 retrospective (n=1,055,800 patients) studies.

Study types and their aims, along with demographic, methodology of each and results are presented in Table 1 [2-39].

Twenty three prospective (n=1,449,992 patients; 99.9%) and nine retrospective (n=1,043,266 patients; 98.8%) studies showed a relationship between PTSD and CVD.

Table 1: Studies taken into consideration.

Author	Study type and aim	No. of patients	Methodology	Results
Scherrer JF et al., 2020 [2]	Prospective study Primary objective:estimate the risk of incident CVD (CVD) in patients with vs. without a clinically meaningful PTSD (PTSD) improvement. Secondary objective: if results differed by depression status and age group.	1079	Eligible patients, were 30–70 years old, diagnosed with PTSD and used Veterans Health Affairs PTSD specialty clinics. Patients had a PTSD Checklist score (PCL) ≥ 50 between 2008 and 2012 and a second PCL score within 12 months and at least 8 weeks after the first PCL ≥ 50. Clinically meaningful PTSD improvement was defined by ≥20 point PCL decrease between the first and second PCL score. Patients were free of CVD diagnoses for 1 year prior to index. Index date was 12 months following the first PCL.	Patients with vs. without PTSD improvement did not differ in CVD risk (HR = 1.08; 95%CI: 0.72–1.63). Results did not change after stratifying by age group or depression status.
Kubzansky LD et al., 2014 [3]	Prospective observational To determine if women who develop PTSD symptoms are more likely to gain weight and become obese relative to trauma-exposed women who do not develop PTSD symptoms or women with no trauma exposure	54224	Trauma and PTSD Screening Questionnaire was used to determine whether women present traumatic exposure according to the DSM-IV PTSD diagnosis. These women were divided in 2 separate groups for analysis depending on when trauma exposure/PTSD occurred. Data on weight and height was reported biennially. The BMI was calculated.	If trauma leads to the development of PTSD symptoms, the patient has an increased risk of weight gain. Women with PTSD should be monitored or undergo screening for development of adverse cardiometabolic outcomes. It is important to expand PTSD treatments to attend to behavioral alterations.
Bourassa KJ et al., 2020 [4]	Retrospective study A secondary analysis of a larger intervention study of active duty soldiers with PTSD The aim of this study is to see if first-line exposure therapies are associated with improvements in participants cardiovascular functioning and reactivity compared to not receiving treatment patients.	104	Active duty soldiers with PTSD were randomized to an exposure therapy—either prolonged exposure or virtual reality exposure (VRE) or a waitlist control condition. The interest variables were: change in participants' resting heart rate (HR) and HR reactivity from baseline (prior to randomization) to mid- and post-treatment.	Decreased resting HR (B = -5.06, p = .024) and HR reactivity (B = -2.46, p = .005) from baseline to post-treatment for PE and VRE relative to waitlist. Exploratory analyses found that change in resting HR and HR reactivity were not significantly correlated with either self-reported or clinician-rated PTSD symptom change.
Burg MM et al., 2017 [5]	Prospective study The aim is to investigate the prospective relationship of PTSD to incident hypertension risk and the effect of PTSD treatment on hypertension risk.	194319	Data from a nationally representative sample of 194,319 veterans were drawn from the Veterans Administration roster of United States service men and women. The variables were: incident hypertension, PTSD treatment	The incident hypertension risk independently associated with PTSD ranged from HR=1.12 (95% CI 1.08 – 1.17, p<0.0001) to HR=1.30 (95% CI 1.26 – 1.34, p<0.0001). The interaction of PTSD and treatment revealed that treatment reduced the PTSD associated hypertension risk (e.g., from HR=1.44 [95% CI 1.38 – 1.50, p<0.0001] for those untreated, to HR=1.20 [95% CI 1.15 – 1.25, p<0.0001] for those treated)
Dennis PA et al., 2014 [6]	Prospective study The aim o this study is to demonstrate that: 1) PTSD symptoms would be associated with lower HRV; 2) PTSD symptoms would be associated with greater smoking, higher rates of lifetime alcohol dependence, higher rates of abdominal obesity, and more sleep disturbance; and 3) each of these behavioral risk	227	Short-term laboratory-based and 24-hour ambulatory measures of HRV were collected from 227 young adults (18-39 years old), 107 of whom were diagnosed with PTSD. They assessed the relationship of PTSD symptoms with HRV along with potential behavioral health mediators.	PTSD symptoms were associated with reduced HRV, β = -.21, p = .002. This association was reduced in models that adjusted for cigarette consumption and history of alcohol dependence, and was rendered non-significant in a model adjusting for sleep disturbance. Abdominal obesity was not a

Author	Study type and aim	No. of patients	Methodology	Results
	factors would partially mediate the association between PTSD symptoms and HRV.			significant mediator.
Chang JC et al., 2017 [7]	Prospective study The present study estimated incident PTSD and comorbid diseases for over a decade in a cohort from a community-based integrated screening program.	76417	The cohort was derived from a population of about 390 thousands adults (aged 30 years and above) in the northeastern part of Taiwan. The enrolled participants were interviewed to collect social demographics, health behaviors (e.g., smoking or alcohol drinking), and family history of major illnesses (e.g., psychiatric disorders).	Compared with non-PTSD participants, those with PTSD tended to be female, younger, more highly educated, non-smokers, and non-drinkers. Furthermore, participants with PTSD had a higher proportion of CVD.
Meli L et al., 2018 [8]	Prospective study They tested whether younger age was associated with greater threat perceptions during ACS evaluation in the ED and greater posttraumatic stress symptoms (PSS) in the frst week after ED enrollment.	871	Participants completed measures of demographics, including age, sex, and race/ethnicity, and perceived threat during evaluation for suspected acute coronary syndrome in the ED. During inpatient stay or by phone after discharge (median 3 days after enrollment), participants reported PSS (i.e., symptoms of re-experiencing and/or avoiding reminders of the trauma, and hyperarousal) in response to the event that brought them to the emergency department.	Younger, versus older individuals are at risk for greater PSS after acute coronary syndrome evaluation, and elevated perceived threat partially mediated this association.
Rosman L et al., 2019 [9]	Retrospective study They assessed the association between PTSD and incident transiemt ischemic attack (TIA) and ischemic stroke	987855	They assessed the incidence of TIA and ischemic stroke in a cohort of 987855 young and middleaged Veterans (mean age of 30.29±9.19 years; 87.8% men, 64.4% white) who first accessed care through the Veterans Health Administration from October 2001 to November 2014 and were free of TIA and ischemic stroke at baseline.	PTSD was significantly associated with new-onset TIA (hazard ratio [HR], 2.02; 95% CI, 1.62–2.52) and ischemic stroke (HR, 1.62; 95% CI, 1.47–1.79). The effect of PTSD on ischemic stroke risk was stronger in men than in women (HR, 0.63; 95% CI, 0.47–0.86; P=0.003), but no effect of sex was found for TIA.
Giesinger I et al., 2020 [10]	Prospective study To assess whether 9/11-related probable PTSD is associated with increased mortality risk	63666	PTSD assessments at baseline (wave 1: 2003-2004) and 3 follow-up time points (wave 2: 2006-2007, wave 3: 2011-2012, wave 4: 2015-2016). PTSD was defined using the 17-item PTSD Checklist–Specific (PCL-S) self-report measure (score≥50) at each wave (waves 1-4	Comparable findings between responders and civilians suggest that 9/11-related PTSD is associated with an increased mortality risk.
Lima BB et al., 2020 [11]	Prospective study. To evaluate the association of PTSD with mental stress–induced myocardial ischemia among individuals who survived a myocardial infarction (MI).	303	Participants had a verified history of MI within 8 months. Patients received technetium 99m–labeled sestamibi myocardial perfusion imaging at rest, with mental stress (ie, a speech task) and conventional stress (ie, exercise or pharmacologic)	PTSD was associated with the development of myocardial ischemia with mental stress.
Lima BB et al., 2019 [12]	Prospective study The aim is to demonstrate that survivors of a myocardial infarction (MI) who have PTSD would show an enhanced inflammatory response to acute psychological stress compared to those without PTSD.	271	Individuals with a verified history of MI within 8 months and a clinical diagnosis of current PTSD underwent a mental stress speech task. Inflammatory biomarkers including interleukin-6 (IL-6), high-sensitivity C reactive protein (HsCRP), matrix metallopeptidase 9 (MMP-9), intercellular adhesion molecule	MI patients with current PTSD exhibit enhanced IL-6 response to psychosocial stress, suggesting a mechanistic link between PTSD and adverse cardiovascular outcomes

Author	Study type and aim	No. of patients	Methodology	Results
			(ICAM)-1, vascular cell adhesion molecule (VCAM)-1 and monocyte chemoattractant protein (MCP)-1 were measured at rest and 90 min after mental stress.	
Britvic D et al., 2015 [13]	Retrospective study The aim of this study was to investigate the differences in the prevalence of somatic diseases among combat veterans and their contemporaries who were not exposed to the traumatic experience at the battlefield, and to determine whether socio-demographic factors, exposure to war-time trauma and/or injury might predict individual somatic diseases	1326	501 male combat veterans with posttraumatic stress disorder (PTSD) and the corresponding control group of 825 men who were not exposed to combat experience. All participants were assessed systematically.	Veterans with PTSD suffered more often from cardiovascular, dermatological, musculoskeletal, pulmonary and metabolic diseases than corresponding control subjects who were not exposed to combat experience. PTSD as a result of exposure to war trauma increases the likelihood of developing somatic diseases.
von Känel R et al., 2021 [14]	Retrospective study This study explored whether a preventive behavioral intervention leads to a decrease in myocardial infarction-induced PTSS between two follow-up assessments.	104	104 patients with MI were randomized to a 45-min one-session intervention of either trauma-focused counseling or stress counseling (active control). Sociodemographic, clinical, and psychological data were collected at baseline, and PTSS were assessed with the Clinician-Administered Post-traumatic Stress Disorder Scale 3 and 12 months post-MI.	PTSS severity showed no change over time from 3 to 12 months post-MI, either in all patients or through the intervention.
Agarwal S et al., 2019 [15]	Prospective study Compared 1-year all-cause mortality and major adverse cardiovascular events in cardiac arrest survivors with and without PTSD symptomatology at hospital discharge.	114	Compare ACM or MACE— hospitalization for nonfatal myocardial infarction, unstable angina, congestive heart failure, emergency coronary revascularization, or urgent implantable defibrillators/permanent pacemaker placements within 12 months of discharge, in case of cardiac arrest suvivors with/without PTSD.	PTSD symptomatology is common after cardiac arrest (CA), and CA-induced PTSS was associated with significantly higher risk of death and cardiovascular events.
Goetz M et al., 2014 [16]	Retrospective study They examined whether PTSD and combat exposure were associated with CIMT (Carotid Intima-Media Thickness) in VietnamWar–era twins after controlling for shared genetic and childhood factors.	465	465 middle-aged twins from the Vietnam Era Twin Registry who were free from CVD were included. PTSD was diagnosed using the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition and CIMT was measured by ultrasound.	Among Vietnam War–era veterans, combat exposure and PTSD are associated with CIMT, though the associations are largely mediated by shared childhood factors
Jiang C, 2018 [17]	Prospective study Revealed the prevalence, associated risk factors, and long-termoutcomes of PTSD in patients after intracerebral hemorrhage (ICH)	64	64 patients with a first ICH were included. PTSD was determined with Diagnostic and Statistical Manual of Mental Disorders (fifth edition; DSM-5), and questionnaires on mental and physical status were used. Patients were followed at 3 and 12 months after ICH	Patients with PTSD were more likely to be female (67% vs. 29%, p ¼ 0.01), and had higher rates of receiving minimally invasive surgery (MIS; 47% vs. 18%, p ¼ 0.04) and and had poorer quality of life and worse stroke-related disability.
Rosman L et al., 2019 [18]	Prospective study The study assessed the incidence of atrial fibrillation over a 13-year period among 988 090 young and middleaged veterans	988090	988090 young and middleaged veterans (mean age, 30.299.19 years; 87.8% men, 64.5% white) free of AF, atrial flutter, or atrial tachycardia at baseline were included and followed for 13 years	Patients with PTSD had a higher overall incidence of AF (P<0.0001) and were more likely to develop AF at a younger age than those without PTSD (P=0.004).

Author	Study type and aim	No. of patients	Methodology	Results
von Känel R et al., 2018 [19]	Prospective study Assessed if trauma-focused counseling prevents the incidence of ACS (Acute Coronary Syndrome)-induced PTSS.	190	190 patients with ACS were randomized to a single session intervention of either trauma-focused counseling or an active control intervention (in first 48 hours) and additional health outcomes were assessed at 3 months of follow-up.	Self-rated PTSS indicated less beneficial effects with trauma-focused (6.54; 4.95–8.14) versus stress counseling (3.74; 2.39–5.08; p = 0.017).
Seligowski AV et al., 2020 [20]	Prospective study Assessed the cardiovascular response to extinction in a sample of trauma-exposed individuals.	51	51 trauma-exposed women underwent a fear conditioning paradigm. Heart rate variability (HRV) was calculated at baseline and during the extinction session.	Higher baseline HRV was significantly associated with greater fear bradycardia during early extinction. Fear bradycardia may be a relevant biomarker in predicting how individuals will respond to extinction-based psychotherapy.
Chen YY et al., 2021 [21]	Prospective study Investigated the associations of PTSD (PTSD) manifestation and early risk factors for cardiovascular physiological measures among adolescence.	606	606 adolescents aged 14-19 years old were included. They were asked to rate their possible trauma experiences and PTSD symptoms via questionnaires. The measured variables were: blood pressure, heart rate and body mass index.	PTSD symptoms had a significant effect on blood pressure and heart rate
Cave B et al., 2019 [22]	Retrospective study Determined, based on prior arterial blood pressure monitoring (ABPM) studies, if PTSD diagnosed veterans have abnormal nocturnal dipping patterns compared with the general veteran population	470	Retrospective chart review was performed on all archived ABPM studies and classified by nocturnal dipping status and BP control rates.	Veterans with PTSD had similar distributions of dipping patterns and rates of overall, awake, and nocturnal hypertension compared with the general veteran population.
Campara TM et al., 2014 [23]	Prospective study The aim of this study was to determine how lipid component act after a certain time distance after effects of multifactorial war stress, in the postwar period among the members of the police department.	300	300 police officers were divided in 2 groups :150 as experimental and 150 respondents as a control group. They were investigated the same way: detailed history, physical examination,complete laboratory evaluation, lipid electrophoresis, ultrasound of the abdomen and Color Doppler of the neck vascular structures.	A significant increase in levels of cholesterol and triglyceride levels was noticed in experimental compared to the control group. The ultrasound of the abdomen showed fatty infiltrated liver in 16% of respondents from the experimental and 2% of the respondents in the control group.
Yu S et al., 2018 [24]	Retrospective study The aim of this study was to investigate the association between 9/11-related PTSD (PTSD), dust cloud exposure, and subsequent development of stroke.	42527	Using data from the World Trade Center Health Registry surveys, they employed Cox proportional hazards regression models to assess the associations.	Incidence of stroke was higher among those with PTSD or intense dust cloud exposure than those without, and it was even higher for those who had experienced both
Baranyi A et al., 2021 [25]	Prospective study 1) Determine whether blood levels of trimethylamine N-oxide (TMAO) vary immediately after acute myocardial infarction (AMI) in patients with/without AMI-induced PTSD symptomatology (2) Investigated whether TMAO is a potential biomarker that might be useful in the prediction of PTSD.	114	114 AMI patients were included. The Clinician Administered PTSD Scale for DSM-5 was used to explore PTSD-symptoms at the time of AMI and 6 months after AMI. To assess patients' TMAO status, serum samples were collected at hospitalization and 6 months after AMI.	Participants with PTSD-symptomatology had significantly higher TMAO levels immediately after AMI than patients without PTSD-symptoms. An elevated TMAO level might be a biological marker for severe stress that is associated with vulnerability to PTSD.
Eslami B et al., 2017 [26]	Prospective study Compared the level of PTSD between adults with and without congenital heart disease and examined the correlates of PTSD	853	Patients were divided in two groups: 347 patients with congenital heart disease and 353 without. PTSD was assesed using PTSD symptom scale	52% of patients with congenital heart disease had PTSD while 48% of those without congenital heart disease had PTSD; p=0.183

Author	Study type and aim	No. of patients	Methodology	Results
Ratcliff CG et al.. 2017 [27]	Retrospective study Examined the association between COPD and CHF in patients with mental health disorder, among them PTSD (based on patient electronic medical records and self-report data)	180	Patients with COPD and CHF were assessed for PTSD (and other mental health issues) using Beck Anxiety Inventory and Patient Health Questionnaire -9	13% of patients with COPD or CHF were diagnosed with PTSD
Jane Irvine J et al., 2011 [28]	Prospective study Assessed the relationship between ICD (implantable cardioverter defibrillator) and PTSD (implantable defibrillator carriers may develop PTSD)	193	96 patients with ICD had received cognitive behaviour therapy while 97 were adressed to standard clinical care; both groups were assessed regarding PTSD and other mental health issues at baseline, 6 and 12 months	Use of cognitive behavioural therapy showed an improvement in PTSD symptoms in patients with ICD (p<0.01)
Shemesh E et al., 2006 [29]	Retrospective study Evaluated the symptoms of PTSD and adherence to aspirine in patients with PTSD which received cognitive behavioral treatment	65	14 patients with a previous MI and diagnosed PTSD: 6 patients received cognitive beahavioral treatment while 8 had received standard care	PTSD symptoms improved in those following cognitive behavioral treatment; adherence to aspirine improved in patients submited to standard care
Gilsanz P et al., 2017 [30]	Prospective study Assessed the association of PTSD symptom severity and trauma exposure to the risk of CVD	49859	The subjects (female nurses enrolled in 1989) were followed up by biennial questionnaires regarding risk factors and health conditions and two supplementary questionnaires assessing exposure to violence, trauma, PTSD symptoms onset, severity and remision	Women exposed to trauma and those with PTSD presented a higher risk of CVD (OR 1.69, 95% CI1.08-2.63) Minimizing the symptoms of PTSD attenuates the cardiovascular risk
Gradus JL et al., 2015 [31]	Prospective study Examined the relationship between PTSD and adjustment disorder and four CVDs: myocardial infarction, stroke, ischaemic stroke and venous thromboembolism	4724	Data from Danish national registries were analysed	There is an association between PTSD and adjustment disorder and all four types of CVD
Remch M et al., 2018 [32]	Prospective study Determined PTSD as a risk factor for myocardial infarction and stroke	6481	Subjects were involved in cleaning the World Trade Centers debris PTSD and depression were self reported, and a 4 year follow up sought for myocardial infarction and stroke among subjects using interview or hospitalizations	The cummulative incidence of myocardial infarction or stroke was higher in PTSD patients
Vaccarino V et al., 2013 [33]	Prospective study Determined the association between PTSD and coronary heart disease	562	Subjects were monizygotic and dyzigotic male twins who were military active in Vietnam era subjected for a 13 years follow up At least one twin of each pair should have had PTSD or depresion or none of them for both but in either case, no previous CVD	In twins with PTSD the incidence of coronary heart disease was higher (p<0.001)
Vidal C et al., 2018 [34]	Retrospective study Determined the risk for CVD in different specific groups	10165	Two datasets that form part of the Collaborative Psychiatric Epidemiology Surveys - the National Latino and Asian American Study and the National Comorbidity Survey Replication were analyzed	Cardiovascular events rate was higher in patients with a diagnosis of PTSD: OR=2.10, 95% CI, 1.32-3.33; all ehnical groups, except for asian responders, had a higher likelihood of cardiovascular events associated with PTSD
Chen MH et al., 2015 [35]	Prospective study Assessed PTSD induced strok	5217	-	PTSD subjects have higher risk for any stroke (HR 3.37, 95% CI 2.44-4.67) and ischaemic stroke (HR=3.47, 95% CI 2.44-4.67)

Author	Study type and aim	No. of patients	Methodology	Results
Goldfinger JZ et al., 2014 [36]	Retrospective study Measured the prevalence of stroke induced by PTSD	535	PTSD Checklist Specific for stroke was applied to adult patients who suffered a stroke or a transient ischaemic attack within 4 years; a PTSD was diagnosed based on score of 50 or more	18% patients had a score of 50 or more Stroke induced by PTSD was more frequently in young patients
Scherrer JF et al., 2019 [37]	Retrospective study Sought for the relationship between PTSD and CVD based on other comorbid associations	11856	Data for 5940 patients with PTSD and 5916 without PTSD, aged 30-70 years, were obtained from electronic health records	PTSD depends on other factors to determine CVD: it was of signifficant statistic value just the association adjusted based on age (HR=1.41; 95% CI: 1.21-1.63) and metabolic conditions (HR=1.23; 95 CI:1.06-1.44)
Cyr S et al., 2021 [38]	Retrospective study Assessed the type of trauma inducing PTSD in patients with CVD	148	37 patients with PTSD and CVD were compared with 111 patients with adjustment disorder and CVD	In 51% cases PTSD was induced by a medical trauma
Spitzer C et al., 2020 [39]	Prospective study Assessed the relationship between PTSD and traumatic stress to carotid plaque and intima-media thickness	3119	General population based study with the patients subdivided in five age groups; each subject underwent a carotid arteries ultrasound PTSD and trauma exposure was assessed by interview	Carotid intima media thickness was higher in subjects with trauma experiences compared to the group without trauma exposure (p<0.001) In the group age 40-49 years carotid intima media thickness was higher in the PTSD group (p=0.005)

ABPM: arterial blood pressure measuement; ACS: acute coronary syndrome; AMI: acute myocardial infarction; CA: cardiac arrest; CHF: congestive heart failure; CIMT: Carotid Intima-Media Thickness; COPD: chronic obstructive pulmonary disease; CVD: CVD; ED: emergency department; HR: heart rate; HRV: heart variability rate; ICD: implantable cardiac deffibrilator; ICH: intracerebral hemorrhage; MACE: Major Adverse Cardiovascular Events; MI: myocardial infarction; PTSD: PTSD; PTSS: posttraumatic stress symptoms; VRE: virtual reality exposure.

DISCUSSIONS

1. PTSD and cardiovascular disease – mechanisms and pathways

1.1. General mechanisms

Emerging literature (Table 2) postulates that there are several mechanisms that contribute to the occurrence of cardiovascular disorders in people suffering from PTSD, none of them acting alone but rather together (Figure 2). It is already known that anxiety and depression as well as other psychosocial factors are modifiers of the calculated total cardiovascular risk as we find in the CVD prevention guidelines [41]. These eventually lead to poor health behavior: sedentary life, obesity, smoking and alcohol consumption that contribute to hypertension, diabetes mellitus and dyslipidemia.

Table 2: Studies for general mechanisms and pathways in PTSD generating cardiovascular disease

Author, year	Conclusion
Lima BB et al., 2019, (12)	MI patients with PTSD exhibit an increased inflammatory response to stress (enhanced IL-6 response), suggesting a mechanistic link between PTSD and adverse cardiovascular outcomes.
Brudey C et al., 2015 (40)	This study demonstrates a link between PTSD and CVD. The renin-angiotensin system, sympathetic overactivation and inflammation contribute to compromised cardiovascular health in PTSD.

CVD: cardiovascular disease; MI: myocardial infarction; PTSD: Posttraumatic stress disorder; IL-6: interleukin 6

Chronic systemic inflammation associated with PTSD is the cause for accelerated atherosclerosis that causes vascular disease (peripheral, cerebrovascular) as well as coronary artery disease. Studies have shown that in patients with PTSD there is an imbalance between proinflammatory and anti-inflammatory cytokines in favor of the first ones, with high levels of IL-1β, TNFα, IL-6 and CRP and low levels of IL-4 and IL-10 [42]. In accordance to this pathway, Lima and collaborators measured the levels of inflammaftory markers in survivors of a myocardial infarction with and without PTSD and found out that, after using a mental stress test (public speaking), levels of IL-6 were 68% higher in the PTSD group (p=0.01) [12].

Exposure to a chronic stress and inflammatory state as that in PTSD induces cardiac structural changes at the level of gap junctions. Studies have shown a decrease in the gap junction protein connexin 43 (Cx43) that is physiologically involved in intercellular communication and thus in action potential conduction through the heart [43]. Decreased levels of Cx43 may be involved in triggering cardiac arrhythmia since this protein is present in both atrial and ventricular cardiomyocytes. Neuroendocrine disturbances are also involved in increasing the risk for CVD. In people suffering from PTSD there is an increased activity of renin-angiotensin system as well as overactivity of sympathetic nervous system, these two together contributing to structural cardiovascular changes, hypertension and its consequences [40].

1.2. PTSD as a two edge sword – PTSD induced by cardiovascular disease

More recently, PTSD is seen as a two edge sword because emerging literature is determining that CVD are acting as its triggers (Table 3). Vice versa, in cardiac patients suffering from an acute coronary event, PTSD can occur after the event. Meli L and her collaborators evaluated the association between PTSD symptoms and age during acute coronary syndrome evaluation in the emergency department.

Table 3: Studies debating cardiovascular disease induced stroke

Author, year	Conclusion
Schultebraucks et al., 2020 [44]	Screening for stroke-induced PTSD in the emergency department has an important role in the potential implementation of primary and secondary interventions to improve patient outcomes.
Chang J-C et al., 2017 [7]	Cardiovascular heart disease, bipolar disorder and majore depressive disorder are associated with an increased risk of developing PTSD.
Meli L et al., 2018 [8]	Younger patients are at risk for greater posttraumatic stress symptoms than older ones, after acute coronary syndrome evaluation in the emergency department.
Lima BB et al., 2020 [11]	In myocardial infarction survivors, PTSD is associated with developing ischemia with mental stress. Traumatic reminders can provoke frequent episodes of mental stress-induced myocardial ischemia, aspect that can lead to worse cardiovascular outcomes in these patients.
von Känel R et al., 2021 [14]	The preventive one-session intervention of trauma-focused counseling had no effect in myocardial infarction survivors (posttraumatic stress symptoms were persistent in the first year after the event).
Agarwal S et al., 2019 [15]	PTSD symptoms are frequent after cardiac arrest. Cardiac arest -induced PTSS is associated with elevated mortality and cardiovascular events.
Jiang C, 2018 [17]	Intracerebral haemorrhage is associated with an increased risk for PTSD in the chinese population, especialy in those who are female, more severely disabled, or received minimally invasive surgery.
von Känel R et al., 2018 [19]	In myocardial infarction survivors, trauma-focused counseling had no effect in preventing acute coronary syndome-induced PTSD.
Greenman PS et al., 2018 [45]	Mental health history, the tendency to stifle negative emotional experiences (known as ‘‘type D personality’’), and social support in patients with heart disease are related to the onset of or protection from depression, anxiety, and posttraumatic stress.
Baranyi A et al., 2021 [25]	An elevated TMAO level might be a biological marker of acute myocardial infarction-related severe stress that is associated with vulnerability to PTSD.
Eslami B et al., 2017 [26]	Half of the adults with congenital heart disease present PTSD diagnosis, which is associated with elevated depressive symptoms and history of cardiac surgery.
Ratcliff CG et al., 2017 [27]	Veterans with cardiopulmonary disease experiencing mental health problems are

	underrecognized and improvment of menthal health screening is necessary.
Jane Irvine J et al., 2011 [28]	The cognitive behavior therapy intervention in combination with usual cardiac care is associated with a greater improvment in psychological functioning of implantable cardiac defibrillator patients.
Shemesh E et al., 2006 [29]	PTSD symptoms and cardovascular risk improved in individuals who received trauma-focused cognitive-behavior treatment.
Edmondson D et al., 2012 [46]	Symptoms of acute coronary syndrome induced PTSD are moderately prevalent and are associated with increased risk for recurrent cardiac events and mortality.

PTSD: Posttraumatic stress disorder; PTSS: posttraumatic syndrome symptoms; TMAO: Trimethylamine N-Oxide

They found that younger versus older subjects are at risk for greater posttraumatic stress symptoms after acute coronary syndrome evaluation and elevated perceived threat partially mediated this association (p < .0001) [8].

An observational prospective cohort study (114 subjects) compared prognosis (1-year all-cause mortality and major adverse cardiovascular events) in cardiac arrest survivors with and without PTSD symptomatology at hospital discharge. After adjustment for demographic and medical covariates, they concluded that cardiac arrest-induced PTSD is associated with greater risk of death and significant cardiovascular risk (HR=3.2; CI, 1.7–6.1). Cardiac arrest induced-PTSD may be considered a distinct type of medical-event induced PTSD, because cardiac arrest survivors rarely remember the event or early post-event period [15].

Recent studies are focusing on acute coronary syndrome-induced PTSD prevention. von Känel and his collaborators concluded that self-rated posttraumatic stress symptoms indicated less beneficial effects with single session trauma-focused counseling versus active control intervention [19]. Implantable cardiac defibrillator (ICD) carriers may develop PTSD and a study conducted on 193 ICD patients showed that cognitive behavior therapy intervention in combination with usual cardiac care is associated with a greater improvment in psychological functioning of these patients [28].

Cerebrovascular pathology can induce PTSD. A study on 64 chinese subjects showed that intracerebral hemorrhage is associated with increased risk of PTSD and the more likely profile of these patients is: female, more severely disabled and subjects that received minimally invasive surgery [17]. Goldfinger measured the prevalence of stroke induced PTSD in patients with a history of stroke or transient ischemic attack within 5 years (mean age was 63 years) and defined the portrait of stroke-induced PTSD patient: young, disabled, with recurrent strokes and comorbidities [36].

A study conducted by Eslami compared the prevalence of PTSD among adults with (347 adults) and without (353 adults) congenital heart disease and found that half of the congenital heart disease patients presented a likely PTSD diagnosis, which was associated with greater depressive symptoms (OR=1.27) and history of cardiac surgery (OR=2.02) [26].

2. PSTD and cardiovascular disease

2.1. PTSD and hypertension

As we know hypertension is a cardiovascular risk factor and also a disorder itself that results from the addition of other risk factors (obesity, sedentarism, smoking, dyslipidemia, alcohol abuse) that, in subjects suffering from PTSD prevail due to bad habits that this people have as a mechanism of coping. Hypertension is the second most studied cardiovascular associated disease in PTSD, after coronary artery disease.

Table 4: PTSD and hypertension

Author, year	Conclusion
Burg MM et al., 2017 [5]	Patients with untreated PTSD have a greater risk to develop incident hypertension.
Chen YY et al., 2021 [21]	PTSD may be a risk factor for elevated blood pressure and heart rate.
Cave B et al., 2019 [22]	There were no differences in distribution of dipping patterns and rates of overall, awake,and nocturnal hypertension in veterans with PTSD compared with the general veteran population.
Sumner JA et al., 2021 [47]	Significant effects of PTSD symptoms were detected for SBP and DBP.

DBP: diastolic blood pressure; PTSD: Posttraumatic stress disorder; SBP: systolic blood pressure

The main studies attributed to hypertension as a consequence of PTSD or a stressful event are presented in Table 4. Burg MM et al. investigated the relationship between PTSD and incident hypertension in a large, nationally representative sample of almost 200,000 Veterans of Operations Iraqi Freedom, Enduring Freedom, and New Dawn and proved that patients with untreated PTSD have a 24-46% greater risk for incident hypertension [5]. Interestingly, another study showed that systolic blood pressure and heart rate modifications present a linear relation with the number of trauma episodes (p =0.003 and p=0.046 respectively), aspect that strengthens the supposition that PTSD is linked to CVD [21]. Despite these evidences, the study of Cave found that there were no differences in distribution of dipping patterns and rates of overall, awake and nocturnal hypertension in veterans with PTSD compared with the general veteran population, but this study had important limitations (retrospective design; variable dipping statuses were not evaluated) [22].

2.2. PTSD and coronary artery disease

Coronary artery disease is the most studied associated pathology to PTSD (Table 5). Proinflammatory status and hyperlipidemia associated with chronic stress contribute to accelerating the process of atherosclerosis thus leading to coronary events. Remch and collaborators found that World Trade Center attack–related PTSD is a risk factor for myocardial infarction and stroke with the same impact in men and women, independent of depression and traditional cardiovascular risk factors [32]. Behavioral mechanisms (smoking, obesity, alcohol overuse) may represent the link between PTSD and elevated risk of coronary artery disease, but the majority of the included studies made adjustments for these variables. All selected studies concluded that PTSD is independently associated with increased risk for incident coronary heart disease and it may be a modifiable risk factor for this pathology [32, 33, 48].

Table 5: PTSD and coronary artery disease

Author, year	Conclusion
Akosile W et al., 2018 [49]	This study demonstrates a possible association between PTSD and incident coronary artery disease.
Gradus JL et al., 2015 [31]	Stress-related psychopathology (including PTSD) is associated with CVD events (myocardial infarction, stroke, ischaemic stroke, venous thromboembolism).
Edmondson D et al., 2013 [48]	PTSD is independently associated with increased risk for incident coronary heart disease and it may be a modifiable risk factor for coronary heart disease.
Remch M et al., 2018 [32]	WTC attack–related PTSD is a risk factor for myocardial infarction and stroke of similar magnitude in men and women, independent of depression and traditional cardiovascular risk factors.
Vaccarino V et al., 2013 [33]	Among Vietnam-era veterans, PTSD is associated with an increased risk of coronary heart disease. This risk is not explained by adverse health behaviors, established risk factors for coronary heart disease or by familial risk factors.

PTSD: posttraumatic syndrome disorder; WTC: World Trade Center

2.3. PTSD and other cardiovascular disease

Stroke represents the leading cause of long term disability and in the same time the leading preventable cause of disability. The mechanisms of the relationship between PTSD and incident stroke are not completely understood until now in the literature (Table 6). One theory is that PTSD implies chronic inflammation, endothelial dysfunction, platelet activation and aggregation, autonomic dysregulation and all of these may have a significant role to atherothrombotic manifestations [9]. The association between PTSD and incident transient ischemic attack (TIA) and ischemic stroke was assessed in a cohort of 987855 veterans (mean age of 30.29±9.19 years) which found that PTSD is associated with a significant increased risk of early incident TIA (HR, 1.61; 95% CI,1.27–2.04) and ischemic stroke (HR, 1.36; 95% CI,1.22–1.52), risk that persisted after adjustment for established stroke risk factors, coexisting psychiatric disorders and healthcare utilization. Also, the same study concluded that PTSD may be a risk factor for stroke at younger ages and also a target for stroke prevention strategies in this category of patients [9].

Table 6: PTSD and other cardiovascular disease

Author, year	Conclusion
Rosman L et al., 2019 [9]	PTSD is independently associated with increased risk for early incident TIA and ischemic stroke in young and middle-aged Veterans. Sex moderated the relationship for adults with ischemic stroke (the effect of PTSD on ischemic stroke risk was stronger in men than in women) but no effect of sex in case of TIA.
Yu S et al., 2018 [24]	9/11-related PTSD and intense dust exposure were each independently associated with an increased risk of stroke.
Kastaun S. et al., 2016 [50]	Studies supporting a link between psychiatric disorders and Takotsubo syndrome. Anxiety and depressive disorders seemed to be more common in patients with Takotsubo syndrome than patients with ST-segment elevation myocardial infarction. Major depression and generalized anxiety disorder were also diagnosed more often in the Takotsubo syndrome cohort than in patients with acute coronary syndrome. Optimal management and treatment of Takotsubo syndrome should involve integration of the psychoneuroendocrinological aspects of the syndrome with the well-established functional abnormalities of the disease.
Edmondson D et al., 2013 [51]	Stroke-induced PTSD is common (1 in 4 stroke/ transient ischemic attack survivors in the first year develop PTSD symptoms, and after that 1 in 9 may experience chronic PTSD) and may represent a new risk factor for recurrent stroke.

Gradus JL et al., 2015 [31]	Stress-related psychopathology (including PTSD) is associated with CVD events (myocardial infarction, stroke, ischaemic stroke, venous thromboembolism).
Remch M et al., 2018 [32]	WTC attack–related PTSD is a risk factor for myocardial infarction and stroke of similar magnitude in men and women, independent of depression and traditional cardiovascular risk factors.
Chen MH et al., 2015 [35]	Patients with PTSD have an increased risk of developing any stroke and ischaemic stroke.
Goldfinger JZ et al. [36]	Stroke-induced PTSD is related with younger age, recurrent strokes, greater disability, and comorbidities.
Perkins JD et al., 2021 [52]	PTSD independently predicts stroke and is seems to be linked to many major stroke risk factors.

PTSD: Posttraumatic stress disorder; PTSS: posttraumatic syndrome symptoms; TMAO: Trimethylamine N-Oxide

Another cohort study that included 6481 subjects who were involved in cleaning the World Trade Centers debris, concluded that PTSD is a potent determinant for myocardial infarction and stroke of similar importance in men and women, independent of depression and traditional cardiovascular risk factors [32]. A longitudinal follow-up study (5217 patients with PTSD and 20868 age – and gender-matched controls; mean age 36.65 years with 79.1% women) aimed to determine the temporal association between PTSD and stroke and found that the PTSD goup presented an increased incidence of any stroke (3.82 versus 1.00 per 1000 person-years, P<0.001) or ischemic stroke (2.07 versus 0.53 per 1000 person-years, P<0.001) at a younger age compared to control group [35].

2.4. PTSD and arrhythmia

The relationship between PTSD and potential arrrhythmia is yet an unknown field because most studies are focusing on other aspects of CVD related to PTSD (Table 7). Trials looking forward to bring in attention this link are rather aiming for changes in heart rate variability (HRV) as a consequence to PTSD than to look for specific arrhythmia. As presented by Dennis and his collaborators in their study conducted on 227 subjects, 107 of whom were diagnosed with PTSD (49 of which were veterans), those in the late category presented a decreased HRV (p=0.002). Interestingly, despite the fact that sleep disorders, abdominal obesity and poor health behavior (alcohol consumption and smoking) were more frequently encountered in the PTSD group compared to nonPTSD group (p<0.001 for each), when adjusting for each of it, analysis was either non-significant (as in the case of sleep disorders and abdominal obesity) or the relationship between PTSD symptoms and decreased HRV was attenuated (for smoking and alcohol consumption) yet, when taken together (smoking, sleep disorder and alcohol consumption), they were responsible for 94% of the effects of PTSD symptoms on decreasing HRV [6].

Table 7: PTSD and arrhythmias

Author, year	Conclusion
Bourassa KJ et al., 2019 [4]	The exposure therapy (prolonged exposure or virtual reality exposure) for PTSD may reduce cardiovascular risk in these patients, improving cardiovascular functioning.
Dennis PA et al., 2014 [6]	The behavioral health risks (smoking, alcohol overuse, sleep disturbance) mediate the association between PTSD and HRV. A healthy lifestyle may enhance the benefits from psychiatric and psychological interventions in PTSD.
Ge F et al.. 2019 [54]	The reduced HRV may be regarded as an endophenotype in PTSD research.
Rosman L et al., 2019 [18]	In this cohort of young and middle-aged veterans, PTSD is associated with an increased risk for early incident atrial fibrillation.
Seligowski AV et al., 2020 [20]	Fear bradycardia may be indicative of greater vagal control (i.e., HRV), both of which are psychophysiological biomarkers that may influence cardiovascular and autonomic disease risk in trauma-exposed individuals.

PTSD: Posttraumatic stress disorder; HRV: heart rate variability

More recently, a prospective study of middle age veterans sought for atrial fibrillation and found out that those with a diagnosis of PTSD had a higher incidence of it (p<0.0001) in unadjusted and adjusted models. Oddly, development of atrial fibrillation was associated with younger ages (p=0.0004) [18].

Arrhythmia may be more frequently in people suffering from PTSD due to a few aspects which are substracted from the former studies: first, there is an increase in sympathetic activity as the PTSD was proved to be associated with increased plasma levels of norepinephrine [53]; secondly, PTSD may generate an unfavorable lifestyle with increasing obesity which favors the appearance of obstructive sleep apnea that, in turns, is also responsible for increasing the sympathetic activity and thirdly, this poor health behavior along with sympathetic overactivity increases the risk of coronary artery disease which can generate life threatening arrhythmia.

3. PTSD – modifiable cardiovascular risk factors and prophilaxy

Posttraumatic stress disorder is associated with a greater risk of cardiometabolic disease (Table 8) and the involved mechanisms are complex: increased inflammation, dysfunction of autonomic nervous system and of hypothalamic-pituitary-adrenal axis, poor behavioral factors (alcohol overuse, smoking, sedentary lifestyle, increased caloric intake) [55]. Rosenbaum's study reinforces this supposition by founding that PTSD patients have a greater risk to develop metabolic syndrome compared to age and sex matched controls (almost twice) and a routine screening for behavioral factors plus an adequate management is needed [56]. Obesity in relationship with PTSD was evaluated in a group of 54224 subjects (ages 24-44 years in 1989) which concluded that women with at least 4 PTSD symptoms had a greater risk of becoming overweight ($p < .001$) [3]. The authors concluded that PTSD treatment should include correction of behavioral alteration and women with a PTSD diagnosis may undergo screening for development of adverse cardiometabolic outcomes [3].

Table 8: PTSD – modifyable cardiovascular risk factors and prophilaxy

Author, year	Conclusion
Bartoli F et al., 2020 [57]	PTSD may be considered a systemic condition and assesment, monitoring and treatment of metabolic variations may determine a significant improvement in its management and prognosis.
Kubzansky LD et al., 2014 [3]	PTSD is associated with an elevated risk of becoming overwight/obese.
Bartoli F et al., 2013 [58]	PTSD is associated with a greater risk of metabolic syndrome.
Goetz M et al., 2014 [16]	Among Vietnam War–era veterans, PTSD is associated with carotid artery intima-media thickness (measure of subclinical atherosclerosis), though the association is largely mediated by shared childhood factors.
Campara TM et al., 2014 [23]	Elevated levels of cholesterol and triglycerides were found in the blood serum of the policemen who have spent the entire war in Sarajevo (experimental), compared to the police officers who spent the war in other areas of Bosnia and Herzegovina (control group). The war determine changes in lipid profile of persons employed at risk professions, such as police officers.
van den Berk-Clark C et al., 2018 [55]	PTSD is associated with reduced healthy eating and physical activity, and increased obesity and smoking. The relation between PTSD, metabolic and CVD may be due to poor diet, sedentary lifestyle, high prevalence of obesity and co-occurring smoking in these patients.
Rosenbaum S et al., 2015 [56]	PTSD is associated with metabolic syndrome (PTSD patients are almost twice as likely to have metabolic syndrome compared to age and sex matched controls).
Spitzer C et al., 2020 [39]	Association between PTSD and atherosclerosis is inconclusive.
Chen YY et al., 2021 [21]	PTSD may be a risk factor for elevated blood pressure and heart rate.
Solter V et al., 2002 [59]	Patients with PTSD have a higher risk of atherosclerosis.

CVD: cardiovascular disease; PTSD: Posttraumatic stress disorder

CONCLUSIONS

Posttraumatic stress disorder has a major impact on the lifestyle and health of subjects exposed to trauma or stress. Cardiovascular disease tend to appear sooner in PTSD diagnosed patients due to a variety of reasons: poor habits, low addressability to health care systems, chronic inflammation status, changes at molecular levels, etc. Otherwise, PTSD tends to be induced by CVD, thus inclining the balance towards whis association. Prevention of PTSD by proper psychological and/or psychiatric intervention in subjects exposed to trauma or stress, including that generated by CVD, might be of help in preventing the appearance or worsening of cardiovascular disorders in this population. Regarding arrhythmic events, we suspect that, PTSD patients may be at risk of developing arrhythmic events, atrial fibrillation probably being the most common. In the light of the above mentioned facts, looking for arrhythmic patients in people suffering from PTSD may be of particular interest in future studies.

Study limitations

Most of the studies analyzed CVD events (defined as myocardial infarction, stroke, ischaemic stroke, venous thromboembolism) not separately on each CVD. Due to the inhomogeneity of the data about CVD type associated with PTSD and the limited data on each type of CVD type (hypertension, coronary artery disease, arrhythmias, or cardiomyopathies like Takotsubo syndrome) and the parameters that was analyzed for this CVD, there was not possible to make an extensive statistical analysis.

Prediction of anxiety, depression and social function among mothers of NICU-hospitalized infants compared to healthy infants' mothers in Baqiyatallah and Imam Hossein Hospitals

Hamideh Molaei[1], Shokofeh Radfar[2], Mitra Radfar[3], Zahra Torabi[4], Sara Radmehr[5]

Abstract: *The main objective of this research is to predict anxiety, depression and social function of NICU-hospitalized infants' mothers compared to healthy infants; mothers. The methodology of research is descriptive in type of correlative and causative-comparative. Population included all mothers of NICU-hospitalized infants and healthy infants' mothers in two Tehran Hospitals from June 2018 to September 2019. The main sample size was randomly selected. Sample size was calculated as 120 at this level based on Cochran's table. The instruments were Beck's (1969) anxiety and depression inventories, and Lekomet et al. (2014) social functioning questionnaire (SFQ). Data was analyzed using analysis of variance, multivariate and step-wise regression. The results implied that those NICU-hospitalized infants' mothers experienced higher levels of depression and anxiety than healthy infants' mothers. Moreover, formers had lower social functioning than latters. On the other hand, depression and anxiety were suitable predictors of mother' social functioning and there was a significant relationship between depression and social functioning mediated by mother's anxiety.*

Keywords: *anxiety, depression, social functioning, infants' mothers, NICU ward*

INTRODUCTION

Low-weight and immature infants are at-risk groups socially and they would experience more physical, psychological and mental diseases than natural infants. Because of physiological specifications they have, immature infants need regulated care to survive and regain their natural growth [1]. On average, 9% of the infants need NICU caregiving processes [2] most of whom are immature infants [3].

Pregnancy, giving birth and postpartum periods are sensitive instances during the woman's life. Thisperiod of time incudes natural and mental transformations in woman's both social roles and familial role [4]. Pre-term parturition is usually traumatic and a source of the parents' distress. This may be recognized as an emotional crisis which often is diagnosed by sense of lacking and sorrow. Sometimes, these statuses remain for a long time after the child birth. For many mothersadaptation to having preterm infants resembles the adaptation to having disabled child [5].

The potential stressor that affect the parents of preterm infants include problems associated with infants' health in hospital as well as after being discharged, reduced responsiveness and concerns about the infants' mental development [6].

Approximately, 28 to 70 percent of preterm infants' mothers experience high levels of the psychological pressures. The damaging influence of preterm infant on mother disrupts her subjective abilities increasing other tensions of having high-risked child. High levels of stress transform and disrupt mother-child interactions. On the other hand, parents with preterm child -may experience wrong and sad ideas as their infant is disabled and is vulnerable against any type of diseases and damages. This parents' idea causes undesirable parents-child interactions and, as a result, leads to their depression and anxiety disorders causing disruptions in

parents cannot play their parenting role well. Consequently, this adversely affects the child's growth and interactive abilities.

One of the variables studied associated with mothers is anxiety. Anxiety is a resisting and chronic phobia of a particular situation or objects which spontaneously is not fearful and this phobia leads the individual to avoid from that situation or object; while individual understands his/her phobia is illogical [7]. Anxiety is referred to as a part of every human's life and everyone experiences it to some balanced extent. To this extent, anxiety is deemed a compromised response [8]. Lack of anxiety may expose individuals to significant risks and issues but anxiety may reach chronic and constant aspects. In this case, this can no longer be a compromised response but it has to be taken as a failure, uncompromised reaction or extensive despair which established a large spectrum of cognitive and physical disorders rather than unjustified phobias [9]. There have been various definitions provided for anxiety. In definition, "excessive phobia in real or imaginative situations" is anxiety. However, anxiety and phobia are similar in many aspects, they indicate apparent differences. Phobia signifies adverse event occurring or experience which will occur soon while anxiety signified an unjustified phobia. Main feature of anxiety is concern including worrying excessively in situations with uncertain outcomes. Excessive concern is harmful since it disrupts the problem-solving capability [10]. Generally, anxiety means resisting and chronic phobia of something or of situations which in fact are not damaging. Such phobialeads to acute tendency to avoid anxious situations; however, individual understands his/her phobias and avoidance are illogical [11].

Studies on epidemiology of this disorder implied that about 8-12% of children and 5-10% of adolescents are exposed to one of the criteria of anxiety disorder diagnosis to the extent that their natural and daily life and functionality are disrupted. This is while girls experience higher levels of anxiety than boys [12]. These issues are often manifested more from pre-school years and highlightedduring the school years behaviorally [13]. Typically, anxiety accompanies with other problems such as eating disorders and substance abuse. Anxious children are less academically achieved and successful, experience interpersonal relationship with same-aged children and are weak in social abilities. Excessive absences during school years and defective relationship with same-aged children will result in future in weak job adaptation and issues associated with self-image as well as psychological disorders [14].

General forms of anxiety disorders are separation anxiety which is diagnosed by excessive level of anxiety due to being distanced from main caregivers, generalized or extended anxiety, phobia of open spaces, social phobia which includes excessive anxiety due to being judged by others or behaviors in a group, phobia disorders which are diagnosed by unpredictable fearful reactions, particular phobias like phobia of objects, animals or particular situations, OCD disorder which is diagnosed by constant and iterative thoughts and habitual behaviors, post-trauma stress disorder which is the result of a shocking event like disasters, sexual rape or death of someone [15].

Howeverall disorders share the anxiety as their main feature, contextual or particular situational factors make them isolated. Particular phobias as King, Hin and Elending (2005) put refer to a wide range of phobias including the five groups mentioned below:

- Zoophobia
- Nature phobia
- Ampule phobia
- Situational phobias
- Other types of phobia [16]

The other variable studied in this research is depression. Depression is a prevalent illness to the extent which is called psychiatry cold. At any certain time section, 15-20% of adults suffer from depressive signs significantly and at least, 12% have got depression to the extent they need therapy. It is guessed that about 75% of hospitalized cases in Psychiatric hospitals consist of depressed cases. Due to reasons not clarified yet, depression among women is approximately two times more than men in western societies [17].

It seems impossible that only one factor can explain depression, but depression is result of several factors interactions. It is shown that depression starting point and development depends on various variables like biology, background of depression, socio-psychological variables and environment among which followings are mentioned:

- Neurotransmitters dysfunction
- Depression background or alcoholism in family
- Losing parents during childhood
- Being neglected by parents
- Current negative life events
- Marrying a criticizer or aggressive spouse
- Lack of closed and reliable relationship
- Lack of social support
- Lack of long-term sense of being valuable

Scientists believe that acute depression is highly prevalent among children. About 2% of children in 6-12 years and 4% of adolescents are depressed. Based on DSM TR-IV criteria for children and adolescents substantial depression, although increasing among children, they are not enlisted among having depressive disorders due to lack of particularity among these age groups. Australian international psychological health and safety provided a checklist of children's behavioral assessment which classified behavioral issues in two general groups and 7 categories. In this classification, anxiety and depression among children are listed as specialized disorders [18].

Practically, four sets of signs are introduced for depression. In addition to behavioral or emotional signs, the intellectual or cognitive signs, motivational signs and physical signs are also mentioned:

- Emotional signs: sense of disappoint, dissatisfaction, lack of values, humility are emotional depression sign but sorrow is the most important and frequent emotional sign of depression.

- Cognitive signs: depressed individual thinks negatively about him/herself. These negative ideas toward him/herself underlie his/her present and future self-image. Depressed individual often experiences low self-esteem. He/she believes in his failure and knows him/herself responsible for the failures. He/she believes in his/her humiliation, incompetence and unworthy.

- Motivational signs: depressed individual face many difficulties to start their activities. In chronic type, lack of response is willingness paralysis. Such patient cannot even take necessary actions for his life. In acute depression, there may be psycho-motor slowness.

- Physical signs: This includes weight loss, reduction or increase of appetite and sexual tendency reduction. Depressed individual is isolated and his body does not attract anything and increasing concerns occur about pains and suffrages [19].

However, there are not sufficient studies on stress and anxiety among NICU-hospitalized infants' parents in Iran and present resources are mostly focusing on effect of psychological diseases on mother due to preterm parturition. Therefore, based on the significance of early diagnosis of anxiety and depression and low social functioning, interventions to increase the preterm infants' parents' coping power, effect of these disorders on mother and infants' health and lack of sufficient studies in Iran, present study aims to compare the anxiety and depression and social functioning of preterm infants' mothers hospitalized in NICU with healthy infants' mothers.

Fliz Arlan &Koel Koyko (2011) in a research in Anadolu University, Turkey, studied the issues of public hospital NICU-hospitalized infants' families and found out that unreliability of adaptation with child's status, executive processes on child and instruments used, lack of visiting or limited time of visiting, lack of sufficient information from medical team, lack of parenting role implementation when child is hospitalized are variables which lead to anxiety among the families of these children and infants [20].

Beheshti Pour et al. (2014) studied compared the stress level of parents with preterm infants hospitalized in NICU and implied that mothers' stress level was higher than that of fathers. Therefore, providing more information and paying more attention to and supporting for parents when their infants are hospitalized should be more focused by medical team particularly the NICU nurses [21].

Jebrayili et al. (2009) in their study investigated the stressors from hospitalized infants' mothers' perspective in Tabriz and indicated that most stressors for these mothers were appearance and behavior of their infants and their parenting role changes [22].

Bastani & Haghighi (2012) in a research found that parents with hospitalized infants in NICU experience depression, disappoint, sense of isolation, stress, anxiety, emotional duality and reduced control on situations [23].

Greene et al. (2015) analyzed depression, anxiety due to prenatal (PPTS) situation among mothers with low-weighted infants hospitalized in NICU and concluded that psychological screening is important in NICU and PPTS symptoms indicated that there may be need for Primiparas therapy for intervention [24].

Bozkurt et al. (2017) studied whether mothers' psychological disorder are effective on preterm infants' birth in pregnancy over 32 weeks and found that mother's depression is negatively related to preterm infants' nervous development during the pregnancy over 32 weeks and during the long-term infants' follow-up of preterm infants, mothers psychological health has to be taken into consideration [25].

METHODOLOGY

Present research is a descriptive study in term of methodology and since the research predicts the anxiety, depression and social functioning of NICU-hospitalized infants' mothers compared to healthy infants mothers, itis a non-pilot study because the inter-variables associations are not changed. This research compares the anxiety, depression and social functioning of NICU-hospitalized infants' mothers with healthy infants' mothers; therefore, this study is a causative-comparative one. Population included all mothers of NICU-hospitalized infants and healthy infants' mothers in Baqiyatallah and Imam Hossein Hospitals from June 2018 to September 2019.

Because the population studied was extensive and this was not possible to provide a list of all members of this population, 120 mothers and their infants were selected as sample size using available random sampling in 2 hospitals, Tehran. The sample size was obtained using Cochran's formula used for large populations with reliability coefficient of 0.95 and accuracy coefficient of 0.05 and the final sample size was 120 participants. The information required for this research was collected from primary resources like theoretical studies for theoretic discussions including specialized books, articles, journals and specialized researches and secondary recourses including information and comments obtained from healthy and NICU-hospitalized infants' mothers

To find these comments, a questionnaire -for this purpose was distributed among the participants. The questionnaires included Beck's anxiety inventory (BAI) involving 21 items. The participants answer multiple choice questions as their level of anxiety. This questionnaire includes scoring and scores interpretation table.

This scale measures particularly the chronic signs of clinical anxiety among individuals with high reliability and validity. The internal homogeneity coefficient (Alpha-coefficient) is 0.92 whose validity was confirmed to be 0.75 in a reexamination after one week and items correlation was from 0.30 to 0.76.

Beck's depression inventory (BDI): this scale is a self-assessment 21-item questionnaire which measures the depression symptoms. Each item represents illness sign based on four levels from zero to three as scores. The score zero indicates the lowest level and score three indicates higher level of individuals experiencing depressive signs. The sum of scores of each scale is 0-63. This is administrated for measurement if depression level among individuals older than 13 years.

Social functioning questionnaire: this was administrated in 2014 by Lekomet et al. with 34 items. The main objectives of this questionnaire is to analysis and assess the social functioning dimensions (friendships and social activities, independence in life skills, interaction with others, intimacy, family, communications and social activities at work, work competences, communications and social activities at school/university, educational competences). The reliability of this questionnaire was assessed in SPSS by internal homogeneity (Cronbach's Alpha coefficient). The reliability calculated for this questionnaire was 0.8 which is desirable (Cronbach's Alpha coefficient>0.7).

Demographic information questionnaire: this scale aims to measure and study human population and its changes over time which includes age (age distribution), number or population of a group, growth rate, distribution, gender, level of education, urban/rural population ratio and the basis of this questionnaire is statistics and data. In this research, this information includes mothers' age, child birth status, number of children and infants' gender. To analyze data the SPSS was used.

RESULTS

Demographic information

The results implied that 50% of the participants were healthy and 50% were hospitalized.51.7% of mothers had bachelor's degree and 10.8% of mothers had master and PhD degrees. Most of the participants (72.5%) were first child and 5% were 4th child. 23/3% were mothers with physical or mental illnesses and 76.6% had no background of physical or mental illnesses and in sum, 20% and 80% of participants were hospitalized in women's ward before parturition and after parturition, respectively.

Most of the participants (55%) were hospitalized for oxygen therapy and 5% had genetic problems (physical issues). Generally, 52.5% of mothers were 20-30 years old and 15% were 25 years or older.

H1. There is a significant difference between NICU-hospitalized infants' mothers and healthy infants' mothers in term of anxiety.

To test three first hypotheses, one way ANOVA was used.

Results of ANOVA (Table 1) indicated that there is a significant difference between NICU-hospitalized infants' mothers and healthy infants' mothers in term of anxiety in significance level lower than 0.05.

H2. There is a significant difference between NICU-hospitalized infants' mothers and healthy infants' mothers in term of depression.

Results of ANOVA (Table 2) indicated that there is a significant difference between NICU-hospitalized infants' mothers and healthy infants' mothers in term of depression in significance level lower than 0.05.

H3. There is a significant difference between NICU-hospitalized infants' mothers and healthy infants' mothers in term of social functioning.

Results of ANOVA (Table 3) indicated that there is a significant difference between NICU-hospitalized infants' mothers and healthy infants' mothers in term of social functioning in significance level lower than 0.05.

Table 1: One-way analysis of variance to compare anxiety between NICU-hospitalized and healthy infants' mothers

Variable	Group	Mean	SD	F	P
Anxiety	NICU-hospitalized infants' mothers	35.36	10.11	394.62	0.00
	Healthy infants' mothers	7.60	5.4		

Table 2: One-way analysis of variance to compare depression between NICU-hospitalized and healthy infants' mothers

Variable	Group	Mean	SD	F	P
Depression	NICU-hospitalized infants' mothers	30.9	8.48	278.97	0.000
	Healthy infants' mothers	8.86	5.69		

H4. Anxiety is a desirable predictor of social functioning of mothers.

H5. Depression is a desirable predictor of social functioning of mothers.

To test hypotheses 4 and 5 the Pearson's correlation test and multivariable regression analysis were used. Tables 4 and 5 present that 0.52 of the changes in mothers' social functioning can be justified by anxiety and depression.

Results of the social functioning regression analysis based on depression and anxiety (table 6) implied the significance of regression equation, i.e. the predicted share of social functioning by depression and anxiety is significant.

Based on regression coefficients tale (Table 7), each predictive variable, i.e. depression and anxiety, can significantly predict the social functioning changes.

Table 3: One-way analysis of variance to compare depression between NICU-hospitalized and healthy infants' mothers

Variable	Group	Mean	SD	F	P
Social functioning	NICU-hospitalized infants' mothers	64.96	23.61	197.32	0.001
	Healthy infants' mothers	115.95	15.25		

Table 4: Correlation matrix of anxiety and depression with social functioning of mothers ($P<0.01$, $N=120$)

Variable	Anxiety	Depression	Social functioning
Anxiety	1		
Depression	0.73	1	
Social functioning	-0.63	-0.7	1

Table 5: Results of social functioning regression based on anxiety and depression

Criterion variable	R	R^2	Adjusted R^2	se
Mothers' social functioning	0.73	0.53	0.52	22.32

Table 6: Results of social functioning analysis of regression based on anxiety and depression

Variable	Source of changes	Sum of Squares	Df	Mean Squares	F	Sig. level
Social functioning	Regression	6631.40	2	33158.20	66.56	0.000
	Residue	58293.38	117	498.23		
	Total	124609.79	119			

Table 7: Results of social functioning regression coefficient based on anxiety and depression

Model	Non-standardized coefficients		Standardized coefficients	T	Sig. level
	B	Se	Beta		
Constant	126.90	3.76		33.75	0.000
Anxiety	-0.51	0.18	-0.25	-2.75	0.007
Depression	-1.27	0.22	-0.52	-5.62	0.000

H6. There is a significant relationship between social functioning and depression mediated by the mother's anxiety.

To test this hypothesis, multiple regressions in the hierarchical procedure were used. Here, to achieve the goal of hypothesis 6 i.e. analysis of mediating role of mothers' anxiety, first the anxiety was introduced into the regression equation to predict the social functioning and second, anxiety and depression were introduced into the multiple regressions equation. The results of hierarchical regressions (Table 8) indicated that first, anxiety explained 40% of the social functioning variance and then, anxiety and depression were entered into the regression. The results of multiple correlations changes indicated that 52% of the social functions was predicted by depression*anxiety.

Table 8: Results of social functioning regression based on depression mediated by anxiet0079

Stages	Predictive variable	R	R^2	Moderate R^2	se	Changed R^2
1	Anxiety	0.63	0.40	0.40	25.05	0.40
2	Anxiety*depression	0.73	0.53	0.52	22.32	0.12

DISCUSSION

The results of this research implied that difference of mean scores of two groups of mothers (with healthy infant and with NICU-hospitalized infants) was significant in term of anxiety and equal mean of two groups is rejected. It can be stated that there is significant difference between mothers with healthy infant and with NICU-hospitalized infantsin term of anxiety and anxiety was higher among mothers with NICU-hospitalized infants. In a research in Anadolu University, Turkey, that studied the problems of - NICU-hospitalized infants' families- it was found out that unreliability of adaptation with child's status, executive processes on child and instruments used, lack of visiting or limited time of visiting, lack of sufficient information from medical team, lack of parenting role implementation when child is hospitalized are variables which lead to anxiety among the families of these children and infants.

Difference of mean score of two groups (with healthy infant and with NICU-hospitalized infants) in term of depression was significant and the equal mean score of two groups was rejected. It can be stated that there is significant difference between mothers with healthy infant and with NICU-hospitalized infants in term of depression and depression was higher among mothers with NICU-hospitalized infants. Jebrayili et al. (2009) in their study investigated the stressors from hospitalized infants' mothers' perspective in Tabriz and indicated that most stressors for these mothers were appearance and behavior of their infants and their parenting role changes. In a study on pregnant mothers in Dezfoul, it was observed that it is 3.1 times more probable among depressed women to give low-weighted child than healthy women which was a significant difference statistically. In this research, mean weight and head perimeter were lower significantly among depressed mother's infants than other group [23]. Mean score difference of mothers (with healthy infant and with NICU-hospitalized infants) in term of social functioning was significant and the equal mean score of two groups was rejected. It can be stated that there is significant difference between mothers with healthy infant and with NICU-hospitalized infants in term of social functioning and social functioning was lower among mothers with NICU-hospitalized infants.Explaining this finding, it can be stated that hospitalized infants' mothers are more exposed to the communicational risks. Level of socio-psychological interactions of hospitalized infants' mothers was lower than that of healthy infants' mothers which reduces their social functioning. Explaining why of hospitalized infants' mothers were significantly different from healthy infants' mothers in term of social functioning, it can be stated that based on the formers' situation if vulnerability is addressed, first the individual is non-functioning and then others play role in her lack of desirable functioning. Weak social functioning is associated with limited opportunities of learning, self-esteem, social knowledge and social restrictions. Obviously, socialization process and social functioning obtaining are complicated processes and numerous factors are influential on its transformation. Pregnancy and maternal status are recognized as potentially vulnerable instances for women's social functioning.

There was significant and negative relationship between social functioning and anxiety; therefore, it can be stated that increase in mothers' anxiety reduces their social functioning. So anxiety is a desirable predictor of social functioning among mothers. The results of Beheshti Pour et al. (2014) were consistent with this result.

Beheshti Pour et al. (2014) studied compared the stress level of parents with preterm infants hospitalized in NICU and implied that mothers' stress level was higher than that of fathers [22].

There was significant and negative relationship between social functioning and depression; therefore, it can be stated that increase in mothers' depression reduces their social functioning. So depression is a desirable predictor of social functioning among mothers.

Bastani & Haghighi (2012) in a research found that parents with hospitalized infants in NICU experience depression, disappoint, sense of isolation, stress, anxiety, emotional duality and reduced control on situations [24].

There was significant relationship between social functioning and depression mediated by anxiety and research hypothesis is confirmed. Therefore, it can be stated that it is not simple to distinguish between depression and stress symptoms. These signs sometimes overlap and do not let understanding whether you are depressed or under stress and pressure. Although there are similarities between these symptoms, symptoms of depression are often more intensive and deeper and they may last for some weeks - while stress is experienced only some days. During pregnancy and parturition, deep changes occur in woman's moods due to highly sensitive psychological drivers and they sometimes lead to psychological issues. Postpartum depression can accompany with reduction of mother's activities and disrupts the mother-child relationship and familial activities and constant disruption and lack of diagnosis and early therapy will lead to ineffective adaptation of mother with child, spouse and family and as a result, lack of ability in taking maternal duties. High level of anxiety and stressleads to psychological vulnerabilities. Therefore, hospitalized infants' mothers' anxiety in social functioning after giving birth causes lack of desirable relationship with child and relatives and results in negative reactions and establishes the grounds of social communication reduction among mothers. Behavioral problems prevalence such as weak social behaviors, aggressive behaviors and behavioral disorders are some of the issues the hospitalized infants' mothers experienced.

CONCLUSIONS

Based on the results, parents with chronic child go through predictable emotional stages. First stage is shock of unpredicted disease which generally changes all their life. Next, sadness, sorrow, anger and disappointment occurabout the child who didn't meet his parents' expectations and hopes. Following to these outcomes, parents' social functioning changes particularly among mothers as a predictable outcome and the variables life depression, anxiety and social functioning, as studied in this research, resulted in statistical analysis and significant relationships with NICU-hospitalized infants' mothers.

CLINICAL PRACTICE

Pregnancy outcomes in a patient with Fontan circulation for single ventricle congenital heart disease and aberrant praevia placental lobe

Diana I. Voicu[1], Octavian Munteanu[1,2], Maria Sajin[1], Adrian Dumitru[1], Roxana O. Darabont[2], Catalin Cirstoiu[1,2], Monica M. Cirstoiu[1,2]

Abstract: *Single ventricle heart (SVH) is a very rare congenital heart disease. However, since the introduction of Fontan's intervention, the survival rate of patients with SVH has been significantly improved, increasing the number of women who may become pregnant in this condition. It has been already reported, in isolated case presentations or in some series of patients, that the pregnacy in the context of SVH and Fontan circulation carries a very high risk for first trimester miscarriage, maternal cardiovascular or obstetric complications and for an increased rate of pre-term birth. Therefore, it is an open field of debate weather or not to allow pregnancy in this category of patients. We are presenting the case of a 22 years old patient who underwent two surgeries for SVH: a Glenn procedure when she was 2 years old and the implantation of a Fontan circuit at the age of 16 years. Since the last surgery she was under permanent internal cardiac stimulation. During the pregnancy the patient was hemodynamically stable, with a normal resting oxygen saturation and a good ejection fraction of the single ventricle. However, the evolution of this patient has become even more challenging due to an aberrant praevia placental lobe. This condition brought her to hospital for several episodes of metrorrhagia and uterine contractions. She delivered at 33 weeks of gestation by emergency Caesarian section with a good evolution until discharge, for mother and the newborn. This case is supporting the opinion that pregnancy can be tolerated without important cardiovascular events in patients with SVH and Fontan circulation, unless heart failure or cardiac arrythmia are associated. Nevertheless, the obstetrical complications remain an important problem in pregnancy overcome of patients with Fontan circulation for SVH that can be superimposed with other unfavorable conditions, like aberrant praevia placental lobe in this case. During the management of such particular clinical settings difficult decisions must be taken, including those addressing the antithrombotic therapy that will be covered in the presentation of this case.*

Keywords: *Pregnancy outcome; Cardiovascular pregnancy complications; Fontan procedure; Delivery, obstetrics*

INTRODUCTION

A single ventricle is a heart defect in which one lower chamber does not develop resulting in a one pumping ventricle only and cyanosis. Single ventricle heart (SVH) defects are rare. They occur in about five out of every 100 000 live births [1]. There have been distinguished more features of SVH, but the most frequently encountered is double-inlet left ventricle [2]. Since its description for the surgical management of tricuspid atresia in 1971, the Fontan procedure has become the definitive palliative surgical treatment of SVH. Its principal consists in the deviation of the systemic venous return directly to the pulmonary artery without passing through a subpulmonary ventricle. Contemporary cohorts of surviving patients with SVH in adulthood have undergone modified procedures compared with the original version, of which the most common is a Dacron by-pass connecting the inferior caval vein to the inferior aspect of the right pulmonary artery [3]. Since the

introduction of Fontan's intervention, the survival rate of patients with SVH has significantly improved, increasing the number of women who may become pregnant in this condition. Overtime, patients with SVH and Fontan circulation are developing complications characterised by atrial arrhythmias, thrombo-embolic events and myocardial and even hepatic dysfunction [4-7]. In particular, the lack of subpulmonary ventricle predisposes to a low cardiac output state with pulmonary blood flow dependent on adequate preload [8]. This fragile balance can be overcome during pregnancy, when basal oxygen consumption increases by 50 mL/min at 40 weeks, requering a 30-80% increase in cardiac output [9]. Patients with Fontan circulation have limited resources to take over a volume overload or to increase adequately their cardiac output [10]. Moreover, it has been shown that pregnacy in the context of SVH and Fontan circulation carries a very high risk for first trimester miscarriage, maternal cardiovascular or obstetric complications and for an increased rate of pre-term birth [11]. Therefore, it is an open field of debate wether or not to allow pregnancy in this patients with SVH and Fontan circulation.

Patients with Fontan circulation have a high rate of thromboemebolic events, recorded in about 20% of cases, which seems to be similar in all variants of this operation, with most of the thrombs located in within the venous circulation [12]. However, current guidelines of the European Society of Cardiology adressed to cardiovascular diseases in pregnancy consider that therapeutic anticoagulation should be considered in pregnant women with Folan circulation, but balanced with the risk of bleeding [13].

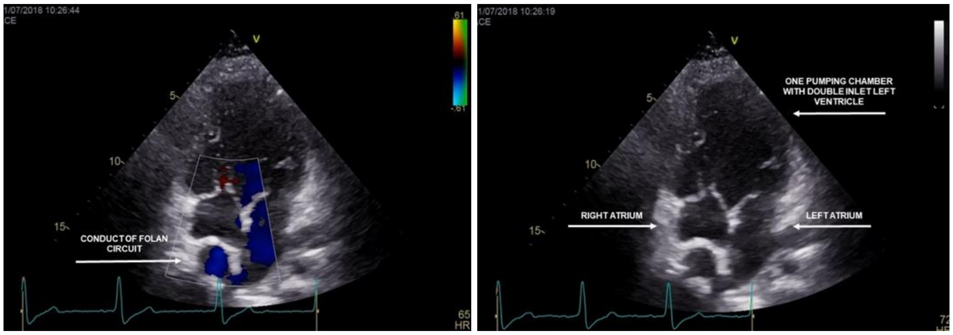
CASE PRESENTATION

We are presenting the case of a 22 years old patient who underwent two surgeries for SVH: a Glenn procedure in order to connect the superior vena cava to the right pulmonary artery when she was 2 years old, and the implantation of a Fontan circuit at the age of 16 years. Since the last surgery she was under permanent internal cardiac stimulation.

Due to the fact that patients with Fontan circulation are considered as having high and very high risk in pregnancy (WHO risk class III or IV) (13) the patient was clearly informed of the possible complications that might occur. However, she gave her written consent for keeping the pregnancy, despite the repeated warnings of the cardiogists and obstetritions.

The patient had a double-inlet left ventricle with an ejection fraction of 57% and a small regurgitation of the right atrio-ventricular valve (Figure 1). Throughout of pregnancy the patient remained hemodynamically stable, with a normal resting oxygen saturation and a good function of the left ventricle, including during delivery. No arhythmia have been recorded. She received antiplatelet therapy with acetylsalicylic 100 mg per day, up to 31 weeks of pregnancy, in order to prevent thromboembolic events.

Figure 1. Transthoracic echocardiography indicating the one pumping chamber with double inlet left ventricle and a part of the Glenn-Fontan circuit

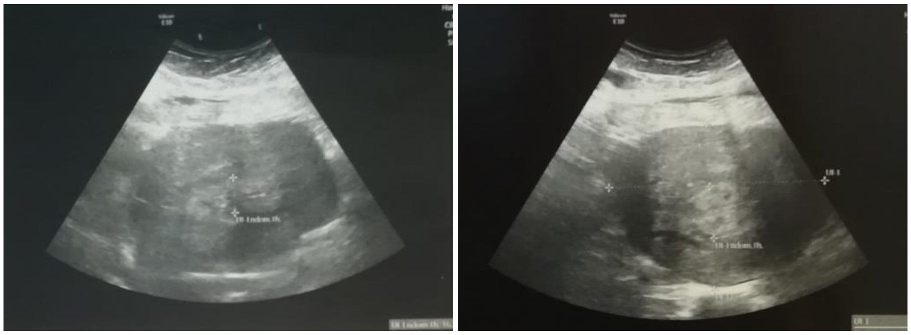


Based on echographic parameters in conjunction with maternal serum biochemistry, the estimated risk for trisomy 21, 18 and 13 was low. The thrombophilic work-up revealed MTHFR C677T homozygote mutation associated with PAI-1 4G/5G. An infection with Ureaplasma Urealyticum was detected, that required antibiotic treatment at 17 weeks of pregnancy.

However, the pregnancy overcome has become more challenging due to an aberrant praevia placental lobe. This condition brought her to hospital for several episodes of metrorrhagia and uterine contractions.

At 33 weeks of gestation the patient was admitted for uterine contractions and vaginal bleeding. She delivered by emergency Caesarean section for placenta praevia and pelvic presentation. The intervention was particularly difficult considering the emergency state of the procedure and the massive bleeding, but during delivery and afterwords, in the Intensive Care Unit, sufficient volume replacement was added in order to maintain adequate preload of Fontan circulation. The postoperative outcome was satisfactory, without further bleedings under prophylactic anticoagulation with low molecular weight heparines. After 12 days from the Cesarian section the patient was suspicioned for an intrauterine residual mass confirmed at echography (Figure 2) for which a guided instrumental revision was performed. The preterm neonate, weighting 1700 g, was registered with 7 on Apgar scale, but with good evolution until discharge.

Figure 2. Ultrasonographic aspect of intrauterine residual mass (transverse section), measuring 27 mm



All the fragments extracted underwent an extensive histopathological analysis which concluded their placental origin with postpartum endometritis and decidual abcesses (Figures 3-5).

The patient received antibiotic therapy with Carbapenems for 10 days. She was discharged on post-operative day 25 in a good condition and without cardiovascular manifestations.

DISCUSSIONS

Since the introduction of Fontan's intervention, the survival rate of patients with SVH has significantly improved, increasing the number of women who may become pregnant in this condition. Based on a report from UK it is expected in the next decade a rise of the adults' number with this condition by 60% [14]. It has been already reported, in isolated case presentations or in some series of patients, that the pregnacy in the context of SVH and Fontan circulation carries a very high risk for first trimester miscarriage, maternal cardiovascular or obstetric complications, including perinatal haemorrhage and for an increased rate of pre-term birth or small for gestational age [15-20]. Due to these reports many authors advised against pregnancy in women with Fontan procedure for SVH. However, in some series of patients with this condition have been identified some categories of patients which might safely evolve during pregnancy, in particular those without heart failure or arrythmias and with a normal resting oxygen saturation [11, 21-23]. The presented case is supporting the opinion that pregnancy can be tolerated without important cardiovascular events in patients with SVH and Fontan circulation in selected situations. Age might have an important role in pregnancy overcome, as long as the risk of cardiovascular complications increases with the duration of time from the palliative intervention.

Antepartum haemorrhage complicates 2–5% of pregnancies, of which approximately one-third are caused by abnormal placental implantations [24]. Placenta previa is characterised by the partial or total covering of the internal os [25]. In certain situations, like in the presented case, only an aberrant lobe may have this aberrant location. Placenta praevia is an obstetric condition that can induce massive antepartum vaginal bleeding. The risk is even higher when accreta and percreta invasion are occuring [26]. It has been reported that the incidence of placenta praevia and abnormal placental invasion has increased in the last years, probably as a result of the large number of C-sections worldwide [25]. However, in our case the patient was primiparous and did not undergo any other previous surgical interventions, but the risk of antepartum bleeding was augmanted by the cardiovascular condition of this patient. Data accumulated over the two past decades are indicating that the maternal and fetal obtetrical complications are high in patients with Fontan circulation, even in those with an estimated low score of cardiovascular complications during pregnancy: a rate of about 50% for obsterical complications and between 70-80% of preterm delivery [11].

Patients with Fontan procedure have a high-risk of thromboembolic events. In pregnancy this risk can be augmented. For this reason our patient had an indication of therapeutic anticoagulation with low molecular weight heparine [13], but her pregnancy overcome was superimposed with an aberrant praevia placental lobe and repeated episodes of metrorrhagia. In this context, the obstetritions and the cardiologists involved in the management of this patient have chosen to give her acetylsalicylic 100 mg per day, because the risk of hemorrhages was too high under heparin therapy. This decision was taken according to the single multicenter, randomized, controlled study which has revealed no differencies in the thrombosis rate of Fontan patients between the use of aspirin and heparin/warfarin [27]. Moreover the postpartum period was complicated by the expulsion of an intrauterine mass. The extracted fragments proved to be placental and infected. Following the prompt guided instrumental revision and the antibiotic cure with Carbapenems, septic complications that could particularly affect Fontan's circulation have been avoided.

CONCLUSIONS

This case is supporting the opinion that pregnancy can be tolerated without important cardiovascular events in patients with SVH and Fontan circulation, unless heart failure or cardiac arrythmia are associated. Nevertheless, the obstetrical complications remain an important problem in pregnancy overcome of patients with Fontan circulation for SVH that can be superimposed with other unfavorable conditions, like aberrant praevia placental lobe in this case. During the management of such particular clinical settings difficult decisions must be taken, including those addressing the antithrombotic therapy, that must be carried on by a multidisciplinary team in order to reduce as much as possible the maternal and fetal morbidity and mortality.

Abstract: *Introduction: Osteoarthritis is considered as the most common joint disease. Sulfur mustard (SM) is a toxic compound, which was applied as a chemical warfare agent by Iraq against Iran veterans during 1980-1988. Chemical veterans suffer from chronic implications caused by sulfur mustard that not only adversely affect their quality of life, but also restrict their working abilities and their participation in social activities. This study aims to consider the prevalence of osteoarthritis disorders among Iranian SM-exposed veterans.*

Methods: In this cross-sectional study, 248 Iranian SM exposed patients were evaluated from 2013 to 2014. Veterans filled a special questionnaire for COPCORD studies and then general and specific rheumatology examinations were applied under the supervision of internists and rheumatologists. The obtained data from 245 filled questionnaires were analyzed by SPSS software and the results were reported as a percentage or mean ±SD.

Results: Bone and joint pain (72%), knee joint pain (52.5%), Joint stiffness (49.2%), and shoulder joint pain (45.8%) were the most common type of complications in these patients. Osteoarthritis in at least one joint was the most common type of osteoarthritis in veterans. 69.5% of veterans had osteoarthritis in at least one joint. Knee osteoarthritis was the second most common type of osteoarthritis, which has been found in 58.4% of all veterans. The prevalence of neck osteoarthritis in all veterans was 23.9%.

Conclusion: The total prevalence of musculoskeletal disorders among Iranian veterans was significantly higher than the average of society.

Keywords: *chemical warfare, osteoarthritis, prevalence, COPCORD*

INTRODUCTION

Osteoarthritis (OA) is considered as the most common joint disease and its main pathologic indication at the tissue level is joint cartilage breakdown. This disease is classified into two main groups: (1) primary or idiopathic osteoarthritis in

which no underlying disease causes the disorder, and (2) secondary osteoarthritis in which an underlying predisposing factor imposes the disease locally or systemically [1]. However, another classification based on the number of involved joints is considered which includes generalized osteoarthritis in which more than 3 joints are involved and also localized osteoarthritis in which less than 3 joints are involved [2, 3]. Identification of predisposing factors gives better insights for the disease pathogenesis. There are various factors such as age, gender, race, genetic, bone density, sex hormones, nutritional status, and environmental factors that can affect the prevalence of OA. Age is the most important risk factor that is not controllable; as it increases, osteoarthritis prevalence rises [4, 5]. The type of joint involvement before 55 years is the same among both sexes; however, when age increases hand joint involvements more likely occur among females but hip joint involvements are more prevalent among men [6, 7]. The prevalence of OA can be increased along with aging and obesity. According to the United Nations, 130 million people will suffer from OA by 2050, of which 40 million will be severely disabled by the disease. The burden associated with OA includes costs for adaptive aids and devices, medicines, surgery, and time off at work. Osteoarthritis prevalence among black and white races is different [8]. The risk of osteoarthritis among individuals who have parents suffering from the disease is significantly higher [9]. Some studies have proposed a reverse relation between osteoporosis and osteoarthritis and some have suggested that bone density increscent is correlated to thigh and knee osteoarthritis but not hand osteoarthritis [10-12]. Endocrine or metabolic disorders such as diabetes, hyperparathyroidism, and acromegaly are in association with osteoarthritis [13]. Nutrition status and antioxidant materials in diets may prevent or postpone osteoarthritis. The damage caused by reactive oxygen species (ROS) is determined through the osteoarthritis trend [14]. Knee osteoarthritis progress among people suffering from vitamin C deficiency is significantly more than those consuming a high amount of this vitamin [15]. Obesity is one of the most important causes of osteoarthritis progress especially in the knee [16]. High pressure on joints due to sport or job, congenital disorders, and inflammatory or infectious diseases are the other affecting factors [16].

The chemical contamination from the wars is one of the main causes of various diseases in veterans. Sulfur mustard [17] is one of the warfare agents which has been utilized during various chemical wars and it was widely applied during the imposed war of Iraq against Iran (1980-88)[18]. The first report on the late implications of SM toxicity among 236 Iranian chemical veterans revealed 78% respiratory, 45% central nerve system, 41% skin, and 36% eye complications. These abnormalities were reported 2-28 months after SM exposure [19].

Chemical veterans are still suffering from the late effects of SM toxicity which negatively impacts their quality of life. More importantly, the progression of their disease restricts their working abilities and participation in social activities. There is little information about the prevalence of osteoarthritis or musculoskeletal disorders among chemical veterans. Since the status of nutrition, medicine, economy, mobility, and generally the lifestyle of the veterans are different from other parts of the society, low bone density or suffering from endocrine and metabolic disorders or chronic infectious disease is more likely to occur among this community [20]. Therefore, the purpose of this study was to evaluate the frequency of osteoarthritis disorders among Iranian chemical veterans who previously exposed to SM using the COPCORD approach.

METHODS

This cross-sectional study was conducted on Iranian chemical veterans in Tehran from 2013 to 2015. For sampling, the initial list of chemical veterans was provided from the lung clinic and medical commission of Baqiyatallah University of Medical Sciences, and individuals who fulfilled the inclusion criteria were entered into the study. Furthermore, according to the coordination of the Veterans and Martyrs Affair Foundation (VMAF), a list of patients who fulfilled the inclusion criteria were selected and invited to participate in the study. The Including criteria were as follows: having documented exposure to sulfur mustard (confirmed by related authorities), male gender, being over 40 years old, moderate and negligible involvement of lungs, and giving consent for participating in the study.

The special questionnaire for COPCORD studies was filled by veterans and the general and specific rheumatology examinations were applied under the supervision of internists and rheumatologists. This questionnaire consisted of demographic questions, complaints about osteoarthritis in the past 7 days, questions about the restrictions, accidents, damages, and external joint symptoms related to musculoskeletal diseases, and also questions in the scope of the treatment detailed examination by specialists and assessing medical histories elucidated the prevalence of different osteoarthritis complications for the mentioned population.

The final part of the questionnaire contained the recorded probable and final diagnosis of the patients who complained about at least one joint (pain, inflation, and stiffness) or external joint pain. If the patient needed more examinations such as radiology in the opinion of the physician, this information was obtained and attached to the questionnaire. Finally, the filled questionnaires were analyzed and the obtained data were revised and after excluding the defaced cases, the questionnaires data were entered into the SPSS software version .20 and the results were described as percentages and mean. The confidentiality of the information of the subjects studied by researchers and project implementers were considered as the ethical considerations of this study. The COPCORD questionnaire used in this study was provided by the Rheumatology Research Center at COPCORD website.

RESULTS

In this study, 245 subjects were evaluated in which 97 patients lived in Tehran and 148 subjects lived in Alborz Provinces. The mean age of the studied population was 51.1 years. Data on demographic information and smoking status can be seen in Tables 1 and 2, respectively.

Table 1: The frequency distribution of studied veterans based on demographic variable

Variable		Number (%)
Marriage status	Single	1 (0.4)
	Married	237 (98.8)
	Spouse dead	1 (0.4)
	Separated or divorced	1 (0.4)
Race	Fars	149 (62.1)
	Azeri	67 (27.9)
	Kurd	11 (4.6)
	Lor	7 (2.9)
	Other	6 (2.5)
Occupation status	Employee	76 (34.1)
	Worker	6 (2.7)
	Retired	76 (34.1)
	Self-employed	49 (22)
	Unemployed	15 (6.7)
	Disabled	1 (0.4)

Table 2: The smoking status of studied veterans

Smocking	Frequency	Percentage	Use average daily	Average of Time (year)
Never	178	75.4	--	--
I am smoking	23	9.7	10.9	19.9
I used to	35	14.8	12.7	6.8

The prevalence of bone and joint complaints in each age group is presented in Table 5. There was no significant difference in the percentage of bone and joint complaints between different age groups. Overall, bone and joint complain (78.4%), bone and joint pain (72%), knee joint pain (52.5%), Joint stiffness (49.2%), and shoulder joint pain (45.8%) were the most common types of bone and joint complains in studied patients.

The percentage of disease intensity and restriction following pain is summarized in Table 3. Most veterans have complained about the intensity of annoying and intolerable pain (73.9%). Furthermore, musculoskeletal pain is getting worse in 66.9% of veterans during activities. Approximately 68.8% of veterans wake up due to musculoskeletal pain.

Table 3: Prevalence of intensity and restriction following pain for complaining veterans

Variable	Percentage
Musculoskeletal pain going worse in the morning	54.1
Musculoskeletal pain going worse during activities	66.9
Waking up because of musculoskeletal pain	68.8
The intensity of annoying and intolerable pain	73.9
Restrictions due to the type or the number of activities in the present or past because of pain, sensitivity, etc.	55.7
Perfect adaptations with problems (pain, sensitivity, etc.)	55.2

Table 4: The relative prevalence of osteoarthritis based on different age groups

Type of the Disease	Age Group (year)			Total
	40-49	50-59	≥ 60	
osteoarthritis at least in one joint (%)	82(69.5%)	72(69.2%)	15(71.4%)	169(69.5%)
dorsal dick osteoarthritis	1(0.8%)	0(0%)	0(0%)	1(0.4%)
spinal osteoarthritis	2(1.7%)	2(1.9%)	0(0%)	4(1.6%)
shoulder osteoarthritis	1(0.8%)	1(0.8%)	0(0%)	2(0.8%)
wrist osteoarthritis	0(0%)	2(1.9%)	0(0%)	2(0.8%)
foot osteoarthritis	1(0.8%)	0(0%)	0(0%)	1(0.4%)
neck osteoarthritis	23(19.5%)	30(28.8%)	5(23.8%)	58(23.9%)
hand osteoarthritis	0(0%)	1(0.8%)	0(0%)	1(0.4%)
hip osteoarthritis	1(0.8%)	3(2.9%)	0(0%)	4(1.6%)
knee osteoarthritis	70(59.3%)	57(54.8%)	15(71.4%)	142(58.4%)

The relative prevalence of osteoarthritis based on different age groups is shown in Table 4. Osteoarthritis in at least one joint was the most common type of osteoarthritis in each age group. 69.5% of veterans had osteoarthritis in at least one joint. Knee osteoarthritis was the second most common type of osteoarthritis in each group. It has been found in 58.4% of all veterans. The prevalence of neck osteoarthritis in all veterans was 23.9%.

The prevalence of osteoarthritis is also considered in men with different age groups (Table 6). Similarly, osteoarthritis in at least one joint was the most common type of osteoarthritis in each age group. Knee osteoarthritis was the second most common type of osteoarthritis in each group.

Table 5: The prevalence of bone and joint complaints in the last 7 days based on the age group.

Type of implication	Percentage in age groups			Total
	40-49 years	50-59 years	≥60 years	
Bone and joint complain	77.1	81	72.2	78.4
Bone and joint pain	73.7	72	61.1	72
Joint inflation	28.8	32	27.8	30.1
Joint stiffness	47.5	50	55.6	49.2
Shoulder joint pain	46.6	47	33.3	45.8
Shoulder joint stiffness	21.2	26	16.7	22.9
Pain due to pressure in the shoulder	30.5	29	16.7	28.8
Elbow joint pain	26.3	22	22.2	24.2
Elbow joint inflation	6.8	8	5.6	7.2
Elbow joint stiffness	10.2	12	11.1	11
Pain due to pressure in Elbow	12.7	17	22.2	15.3
Wrist joint pain	24.6	27	27.8	25.8
Wrist joint inflation	7.6	10	11.1	8.9
Wrist joint stiffness	8.5	14	22.2	11.9
Pain due to pressure in the wrist	14.4	20	16.7	16.9
Pain in the hands and fingers joints	23.7	25	16.7	23.7
Inflation in the hands and fingers joints	12.7	6	11.1	9.7
Stiffness in the hands and fingers joints	9.3	14	11.1	11.4
Pain caused by pressure in the hands and fingers joints	13.6	17	16.7	15.3
Pelvic joint pain	33.1	28	16.7	29.7
Pelvic joint stiffness	11.9	19	11.1	14.8
Pain caused by pressure in the pelvic	19.5	28	22.2	23.3
Knee joint pain	50.8	55	50	52.5
Knee joint inflation	18.6	22	27.8	20.8
Knee joint stiffness	16.9	29	38.9	23.7
Pain due to pressure in the knee	28	34	33.3	30.9
Ankle joint pain	22.9	25	22.2	23.7
Ankle joint inflation	11.9	14	16.7	13.1
Ankle joint stiffness	10.2	18	22.2	14.4
Pain due to pressure in the ankle	15.3	22	16.7	18.2
Toes joint pain	16.9	21	16.7	18.6
Toes joint inflation	5.1	8	16.7	7.2
Toes joint stiffness	5.1	12	16.7	8.9
Pain due to pressure in the toes	12	18	27.8	15.7
Neck joint pain	37.3	39	16.7	36.4
Neck joint stiffness	18.6	21	16.7	19.5
Pain due to pressure in the neck	20.3	29	16.7	23.7
Spine joint pain	47.5	46	27.8	45.3
Spine joint stiffness	22	21	16.7	21.2
Pain due to pressure in the spine	29.7	32	16.7	29.7

DISCUSSION

Musculoskeletal implications negatively affect individuals' health, sanitary, and treatment systems [21]. In a previous study by Joshi and Chopra (2009), they considered the prevalence of osteoarthritis types in 8145 adult subjects in the Pune area located in India. Their results revealed that musculoskeletal pain was the most prevalent type of osteoarthritis in these individuals [22]. The results of the current study demonstrated that the prevalence of musculoskeletal complaints during the past 7 days among veterans is significantly high (78.4%). The most prevalent complaints from the veterans were related to Bone and joint pain, Knee, shoulder joint pains, and joint stiffness. The results of previous studies from different parts of Iran showed that the prevalence of joint complaints in the past 7 days is 54.13%, 41.9%, 42.8%, and 44.7% [23-26]. The comparison of the approached global studies indicated that the prevalence of musculoskeletal complaints in Iran is generally higher than in other Asian countries [27].

Table 6: Prevalence of osteoarthritis among men (Tehran COPCORD results)

Type of the Disease	Age Group (Year)		
	40-49	50-59	≥ 60
osteoarthritis at least in one joint (%)	39%	27%	16.6%
neck osteoarthritis	3.35%	2.41%	1.14%
hand osteoarthritis	7.14%	1.39%	0.5%
hip osteoarthritis	1.99%	0%	0.14%
knee osteoarthritis	36.32%	24.46%	14.49%

Based on the obtained results and final diagnosis of the following study, osteoarthritis, back pain, and pre-arthritis (69.9%, 30.5%, and 27.2%) had the highest frequency of the musculoskeletal diseases among the studied population. This finding confirmed the results of Tehran's study [27]. The results of a previous study on the rural population in Iran showed that approximately 20% of individuals suffered from osteoarthritis in at least one joint. The comparison of COPCPRD results in 17 countries revealed that Iran is second place in regards to osteoarthritis complications (with a frequency of 16.9%) [26[.

The results of this study demonstrated that the most prevalent type of osteoarthritis among veterans is knee (58.4%) and neck osteoarthritis (23.9%), respectively. Interestingly, knee osteoarthritis has been reported as one of the most prevalent rheumatic disorders among the Asian-Oceanic population [23]. The prevalence of knee osteoarthritis was previously calculated to be 5.8% in the rural areas of India, 22-28% in the urban areas of India, 25% in the rural populations in the north of Pakistan, 7.5, 9.2 and 10.6 in the rural, urban slumps and developed urban areas of Bangladesh, and 7.5% in China respectively [28-31]. The results of other studies on the Iranian population demonstrated that the prevalence of knee osteoarthritis in the southeast areas, rural areas, Sanandaj, and the whole country is 18.66%, 19.34%, 26.3%, and 15.5%, respectively [24-26, 28]. Recent studies have indicated that Iran is r ranked third for knee pain among 17 investigated countries [25]. According to previously accomplished data and results of the current research, the incidence of knee pain in veterans is significantly higher than that in the general population of Iran.

In this research, the prevalence of Gout arthritis in veterans was 0.4%. In previous studies, the prevalence of gout arthritis among individuals who lived in Tehran and Sanandaj was 0.13% and 0.12%, respectively [27, 32]. Dawatchi et al. indicated that Iran is ranked 11 among 17 countries regarding the prevalence of rheumatic diseases [25]. Further statistical analysis revealed that Indonesia (1.6%) and Australia (1.5%) had the highest frequency for this disease [25].

CONCLUSIONS

The results of this study described the frequency of musculoskeletal disorders and associated complaints among Iranian chemical veterans. Our data have revealed that the total prevalence of musculoskeletal disorders among Iranian veterans is significantly higher than the average of society. Due to the restrictions of these individuals and specific treatment needs, periodic screening tests, effective and proper nutrition, athletic and therapeutic interventions are strongly suggested to improve musculoskeletal disorders among chemical veterans.

ORIGINAL ARTICLE

Prevalence of rheumatic disorders in Iranian chemical injured patients: a WHO–ILAR COPCORD study

Abolfazl Shakibaee[1], Gholam H. Alishiri[2], Zeynab Ebrahimpour[3], Soraya Shadmanfar[4], Reza Hosseiniara[5], Noushin Bayat[1]

Abstract: *Background: Rheumatic disorders are one of the most prevalent human diseases which commonly become chronic and cause different types of disabilities. Chemical veterans may suffer from chronic difficulties caused by rheumatic disorders that can lead to decrease of their quality of life. The main purpose of this study was to evaluate the prevalence of rheumatic disorders among Iranian chemical warfare patient's long-years after sulfur mustard (SM) exposure.*

Methods: This cross-sectional study was conducted from 2013 to 2014 on 245 Iranian chemical veterans. In order to evaluate rheumatic disorders, a special questionnaire for COPCORD studies were filled by veterans and then general and special rheumatology examinations were applied under the supervision of internists and rheumatologists. Data from all questionnaires were analyzed by SPSS software and the results were reported as percentage or mean ±SD.

Results: Osteoarthritis (69.9%) was the most common complications diagnosed in these patients. After that back pain (30.5%) and pre-arthritis (27.2) were the other popular complications among veterans. The percentage of frozen shoulder and moderate carpal tunnel syndrome was 13.2% and 11.5%, respectively. Tennis elbow and fibromyalgia (3.7%), rheumatoid arthritis (0.8%) and gouty arthritis with 0.4% were the lowest complications among these patients.

Conclusion: Rheumatic associated complications in Iranian chemical injured veterans are higher than the mean of whole community. This data provided the possibility of calculating the disease's burden and making efficient decisions in the sanitary and treatment systems.

Keywords: *chemical veterans, rheumatic disease, prevalence, COPCORD*

INTRODUCTION

Rheumatic disorders are among the most prevalent human diseases. One of seven referring patients to physicians suffer from rheumatic diseases [1]. Several factors such as bacterial infections, life style, and environmental factors can be correlated to rheumatic disorders [2, 3]. This disease can cause different types of important disabilities which in turn adversely influence the quality of life, physical and social activities in affected individuals [4]. It was estimated that ~40% of all chronic diseases and ~54% of long term disabilities are caused by rheumatic diseases [5]. For instance, Disability Adjusted Life Year (DALY) in cases of osteoarthritis was increased from 13275 patients in 1990 to 14230 patients in 2000 [6]. These patients are significantly susceptible to other disorders [7] and diseases like hepatitis B [8].

Back into the 7th decade, the manuscript of the community oriented program for the control of rheumatic diseases (COPCORD) was provided in the non-communicable disease section of WHO [9]. This manuscript describing a model of consumable agenda in rural and urban areas of developed and developing countries, was evaluated in the first meeting of the ILAR and WHO in January 1981 in Genève and formed as COPCORD [10].

COPCORD is one of the most comprehensive epidemiologic studies worldwide. The first stage of the agenda was approached in Iran which was applied by the Rheumatology Research Center of Tehran University of Medical Sciences on the adult population of Tehran's urban areas via cluster sampling method. It was also followed by other studies from other areas of the country in the recent years [11].

A joint study by the Iranian and Bangladeshi researchers with the objective of providing and improving a questionnaire consisting of identification of knee osteoarthritis risk factors in developing countries, reported a pilot survey in the phase III of the COPCORD questionnaire. They suggested that these questionnaires must be validated for identifying knee osteoarthritis among Asian and Oceania populations [12].

Mustard gas (Sulfur mustard) is one of the warfare agents which has been utilized during chemical wars and used by Iraq against Iran during 1980-1988. During Iraq-Iran war, SM injured more 100,000 veterans that many of whom are still suffering from its late effects. Chronic infection, purulent bronchitis, spread tightened trends, bronchial hyper activity, severe asthma, bronchitis obliteran, psychophysiological asthma and vascular-pulmonary problems are the most prevalent implications caused by sulfur mustard exposure in veterans [15, 16]. Chemical veterans may suffer from some chronic difficulties such as rheumatic disorders which can lead to decrease of their quality of life, their working abilities, social relationships and physical activities. However, there is little information about the prevalence of rheumatic disorders among chemical veterans.

Since nutrition, medicine, economic, activity status and lifestyle of the chemical veterans are different from other communities, the frequency of rheumatic diseases among this population may be different.

Therefore, the aim of this study is to evaluate the prevalence of rheumatic diseases among chemical veterans exposed to SM during the imposed war of Iraq against Iran using a community oriented program for the control of rheumatic diseases.

METHODS

This cross-sectional survey was conducted on the 245 Iranian chemical veterans from Tehran and Karaj cities in 2013 to 2015. The veterans who fulfilled the following criteria were included: (1) having a documented history of sulfur mustard exposure (confirmed by related authorities), (2) male gender, (3) being over 40 years old, (3) moderate and negligible involvement of lungs and (4) giving a consent letter for participating in the study.

Sampling in Tehran city was accomplished by introducing the initial list of certain chemical veterans from the hospitalization sections of Baqiyatallah Hospital, lung clinic and the medical commission of the Baqiyatallah University of Medical Sciences. Due to the restrictions of veterans visiting, only the information of 97 chemical veterans from Tehran was obtained successfully.

For sampling in Karaj city, a list of 1050 chemical veterans was prepared by the coordination of the Alborz province Veterans and the Martyrs Affair Foundation (VMAF) primarily. From the initial list, 148 subjects who fulfilled the inclusion criteria were invited to participate in the study. In order to evaluate rheumatic diseases, special questionnaire for COPCORD studies were filled by veterans and general and special rheumatology examinations were applied under the supervision of internists and rheumatologists.

All data from 245 filled questionnaires were analyzed by SPSS software and the results were reported as percentage or mean ±SD. The COPCORD questionnaire used in this study was provided by the Rheumatology Research Center at Baqiyatallah University of Medical Sciences.

RESULTS

Among the 245 studied veterans, 97 subjects were resident in Tehran and 148 patients lived in Alborz Provinces. The mean of age and BMI of all patients was 51.1 years and 26.7 kg/m^2, respectively. Other demographic data such as smoking habitat, race and marriage status are presented in Table 1.

After examinations by specialists and assessing medical histories, diseases which were responsible for the mentioned implications were diagnosed. Figure 1 shows the percentage of complaints associated with rheumatoid arthritis in SM-exposed veterans. Osteoarthritis (69.9%) was the most common complications diagnosed in these patients.

After that back pain (30.5%) and pre-arthritis (27.2) were the other popular complications among veterans. The percentage of frozen shoulder and moderate carpal tunnel syndrome was 13.2% and 11.5%, respectively. Tennis elbow and fibromyalgia (3.7%), rheumatoid arthritis (0.8%) and gouty arthritis with 0.4% were the lowest complications among these patients.

The frequency of rheumatic disease associated complications for each age group and the whole studied population can be seen in Tables 2, 3 and 4.

Table 1: The frequency distribution of marriage status, race, occupation status and smocking background in veterans

Variables				Frequency	Percentage
Marriage status	Single			0.4	1
	Married			98.8	237
	Spouse dead			0.4	1
	Separated or divorced			0.4	1
Race	Fars			62.1	149
	Azeri			27.9	67
	Kurd			4.6	11
	Lor			2.9	7
	Other			2.5	6
Occupational status	Employee			34.1	76
	Worker			2.7	6
	Retired			34.1	76
	Self-employed			22	49
	Unemployed			6.7	15
	Disabled			0.4	1
Smoking		**Average of time (years)**	**Daily average use**		
	Never	--	--	75.4	178
	I smocked	19.9	10.9	9.7	23
	I used to	6.8	12.7	14.8	35

Table 2: The relative frequency of pre-arthritis (at least one type) based on different age groups

Age Group (Years)	COPCORD Males Tehran	Veterans	
	%	%	Frequency
40-49	4.19	23.7	28
50-59	7.21	31.7	33
Over 60	10.78	23.8	5
Total	---	27.2	66

Table 3: The relative frequency of moderate carpal tunnel syndrome based on different age groups

Age Group (Years)	COPCORD Males Tehran	Veterans	
	%	%	Frequency
40-49	0.69	11.7	14
50-59	0.69	12.5	13
Over 60	0.28	4.8	1
Total	---	11.5	28

Table 4: The relative frequency of rheumatoid arthritis based on different age groups

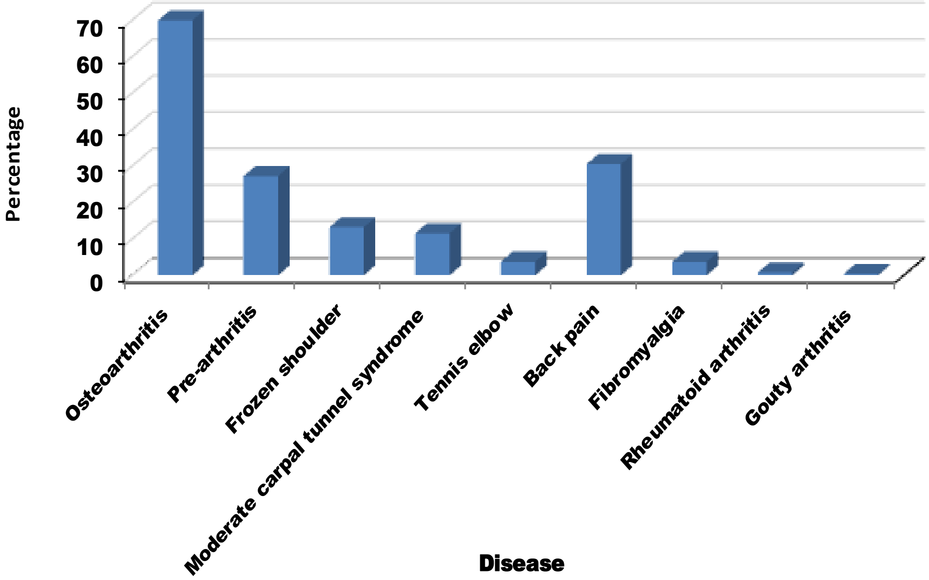
Age Group (Years)	COPCORD Males Tehran	Veterans	
	%	%	Frequency
40-49	0.25	0.8	1
50-59	0	0	0
Over 60	0	4.8	1
Total	---	0.8	2

The percentage of pre-arthritis in veterans with 51-59 years-old was higher than that in other age groups (Table 2). Veterans over 60 year-olds showed higher percentage of rheumatoid arthritis (4.8%) and moderate carpal tunnel syndrome (4.8%) compared to the other age groups (Table 3 and Table 4).

DISCUSSION

With the objective of identification, prevention and controlling rheumatoid diseases in the developing countries, WHO and ILAR coordinated in 1981 in order to organize COPCORD [9]. This program has been performed in many countries such as Australia, Bangladesh, Brazil, Chili, China, Cuba, Indonesia, India, Kuwait, Malaysia, Mexico, Pakistan, Egypt, Guatemala, Lebanon, Tunisia, Philippines, Tailed, Vietnam, as well as Iran [9, 12, 17-30].

Figure 1: The frequency of diagnosed joint diseases in chemical veterans



Degenerative joint diseases are among the most prevalent rheumatoid disorders in human populations worldwide [31]. Studies indicating the relationship between age and knee osteoarthritis have demonstrated that along with aging, some levels of degenerative changing occur in joints such as knee joints [32]. In spite of several studies which emphasized rheumatoid disorders in Iran, our study is the first survey in which the percentage of rheumatoid disorders was evaluated in Iranian chemical veterans. Our data have revealed that osteoarthritis and pre-arthritis with the prevalence of 69.9% and 27.2% were the most prevalent among the studied population, respectively. The results of a study conducted in Tehran confirmed these results [11]. The results of a study on rural areas of Iran revealed that about 20% of patients suffered from osteoarthritis in at least one joint. Also, the COPCORD results of 17 countries indicated that with the prevalence of 16.9%, Iran stands in the second level of osteoarthritis prevalence [33].

Our results showed that the prevalence of pre-arthritis or soft tissue rheumatoid among veterans was remarkably higher than the general population of Iran. Similarly, previous studies in Iran showed that the prevalence of pre-arthritis in Sanandaj, Tehran and for the whole country was 5.5%, 4.62% and 4.6%, respectively [11, 24, 34].

The prevalence of rheumatoid arthritis in our study was 0.8%, which was close to the results reported previously in the southeast areas of Iran (0.98%) [35]. Meanwhile, the prevalence of rheumatoid arthritis among veterans was higher than the population of Tehran (0.33%) and Sanandaj (0.51%) [11, 24]. The comparison of the following results with the general population of other countries revealed a higher prevalence of the mentioned diseases among veterans.

The prevalence of gouty arthritis in this study was 0.4%, while it was previously reported as 0.13% in Tehran and 0.12% for Sanandaj [24, 36]. Dawatchi et al. indicated that Iran is ranked 11th among 17 countries in regards to the prevalence of this disease [34]. The other statistics revealed that Indonesia (1.6%) and Australia (1.5%) had the highest frequency for this disease [34].

CONCLUSIONS

This study evaluated the prevalence of rheumatic complications and disorders among Iranian chemical veterans community. Our results have demonstrated that total rheumatic complaints and disorders among this population are higher than the mean of the whole community. These data provided the possibility of calculating the disease's burden and making efficient decisions in the sanitary and treatment systems. Due to the restrictions and special treatment needs of this community, approaching periodic screening tests, designing beneficial nutrition, athletic and treatment interventions can improve and meliorate rheumatic diseases among chemical veterans. Therefore, this study has performed the initiating steps in the case of identifying mentioned complications among chemical veterans and following steps must be taken to investigate the preventing applications of rheumatoid disorders among this population. Also, medicine prescription as well as the intervention of the prescribed drugs must be evaluated through a widespread study.

Primary retroperitoneal tumors – A brief classification and differential diagnosis

Alexandru Cherciu[1], Lucian Iorga[1], Radu Anghel[1], Dragos Marcu[1,2], Raluca S. Costache[1,2], Ioana Bratu[1], Maria Manea[1]

Abstract: *According to literature the primary retroperitoneal malignant pathology is rare, representing less than 0.5% of all malignancies. In spite of its low incidence, this pathology often proves challenging in terms of diagnosis and treatment. The most com¬mon retroperitoneal malignancy is represented by lymphoma that accounts for approximately 33 % of the retroperitoneal malignancies. Other frequent retroperitoneal tumors are sarcomas: liposarcomas, leiomyosarcomas and malignant fibrous histiocytoma (in order of incidence). We have analyzed the existing data regarding the most common primary retroperitoneal tumors in order to realize a brief classification and their differential diagnosis considering their clinical, imagistic, histopathological and molecular characteristics.*

The technological developments that have been made over the years in terms of imaging investigations, as well as in biomelecular and cytogenetic studies have offered new possibilities for of assessing a retroperitoneal mass in order achieve more precise informations that can guide physicians to better distinguish between different types of retroperitoneal tumors and therefore their therapeutical protocol.

Keywords: *retroperitoneal tumors, diagnosis, imaging investigations*

INTRODUCTION

According to literature, approximately 70% – 80% of the primary retroperitoneal neoplasms it is estimated that are malignant, these tumors accounting for 0.1%–0.2% of all malignancies [1, 2]. These retroperitoneal masses can be divided into solid and cystic tumoral masses [3-5]. Because the treatment options vary, it is useful to be able to distinguish these masses and to diagnose them clearly in order to choose the correct therapeutical protocol. Imaging investigations and biopsy play a crucial role in establishing the tumors characteristics in terms of tumour content, size, shape, wall thickness, the presence of intratumoral septa, calcification, fat, necrosis, detecting the extension of the disease in nearby structures and also distant metastases, as well as in predicting the patients prognosis [1, 6, 7].

SOLID RETROPERITONEAL TUMORS

Solid retroperitoneal neoplasms can be split into four groups: 1. mesodermal neo-

plasms; 2. neurogenic tumors; 3. germ cell, sex cord, and stromal tumors; 4. lymphoid and hematologic neoplasms [8].

Mesodermal Neoplasms

Retroperitoneal neoplasms are predominantly of mesodermal origin, the most frequent tumors located in the retroperitoneum being liposarcomas, leiomyosarcomas and malignant fibrous histiocytoma.

Retroperitoneal sarcomas represent approximately 0.2% of all malignancies, being more frequently discovered during the 6th decade of life. Quite often these retroperitoneal masses are found incidentally during imaging investigations, especially in early disease stages when the patient has no alarming sings, nor symptoms that could alert the patient and raise a question mark. Otherwise, a great percentage of retroperitoneal tumors are detected in advanced stages, when the tumor has important dimensions, often being associated with symptoms related to the nearby organ compression or invasion and therefore being less possible to achieve a complete and oncological surgical resection. The rate of relapse in such cases is high, often these patients will develop distant metastases, more frequently in the lungs, liver, bones and brain [1, 2].

Liposarcoma

Liposarcoma is the most common soft tissue sarcoma encountered in adult patients.This fatty cell tumor usually develops in middle-aged individuals as a mass of submucosal tissue that grows easily without pain and ulceration, yet some lesions can grow rapidly and become ulcerated. The most recent classification of sarcomas identifies five categories of liposarcomas: well differentiated, with adipocytic, sclerosing, and inflammatory subtype, dedifferentiated, myxoid, round cell, pleomorphic.

The histological type appears to be closely related to the anatomical distribution, so the well-differentiated liposarcoma appears more frequently in the soft tissues of both limbs and retroperitoneum, whereas the mixoid/round-cell liposarcomas and the pleomorphic liposarcomas have a striking predilection for limbs.

The tumor usually grows slowly over time, leading to progressive and diffuse abdominal distention and to other symptoms that appear to be secondary to the adjacent organ compression. Physical examination can prove itself to be inconclusive (especially in early stages when the tumor is small and without secondary signs nor symptoms), but in advanced stages (when the tumor has important dimensions) it may prove to be a useful tool in terms of raising the suspicion of a retroperitoneal mass.

Laboratory studies have demonstrated that cytogenetics have an important role in diagnosing lipomatous tumors based on the differences of chromosomal abnormalities between tumor types. The lipoblastoma usually exhibits modifications of bands 8q11-13 and the gene PLAG1 has been involved as the target of chromosomal changes [9].

Another important method used for evaluating these types of tumors is represented by imaging investigations. For example, computer tomography (CT) scanning has proven to be superior to magnetic resonance imaging (MRI) when we are investigating a bone erosion and demineralization, whereas MRI provides information's about the limbs characteristics, describing the fatty nature of the tumor. Liposarcomas usually have well-defined and mostly lobulated margins. The well-differentiated liposarcomas are formed of mainly fat tissue with septa or nodules. Myxoid liposarcomas are described as having a pseudocapsule with a homogeneous or heterogenous aspect. Pleomorphic tumors have a markedly heterogeneous structure. Another imagistic technique that can be used for the diagnosis process is angiography. This invesigation can demonstrate tumor malignancy on the basis of a prominent vascular component, therefore having an important value in planning the therapeutical protocol. The diagnostic procedure for liposarcoma is biopsy. For large (>3 cm) and deep tumors, the diagnosis implies open incisional biopsy accompanied by definitive resection. Fine-needle aspiration (FNA) should be followed by immunohistochemical and histological examination [10, 11].

Immunohistochemical examination is used for excluding other types of sarcoma. Lipid staining may be helpful, although oil red O stains or Sudan black are insufficient for diagnosis. Helpful stains include the following [12]:

- S-100 – Positive results in fat cells and lipoblasts;
- Alpha-1-antitrypsin – Positive results in malignant fibrous histiocytomas;
- Desmin – Positive results in leiomyosarcomas;
- Myoglobin – Positive results in rhabdomyosarcomas;
- Adipophilin stain to document lipid content in the cytoplasm of the neoplastic cells using formalin-fixed paraffin-embedded issue.

Histologically the identification of lipoblasts is decisive for the diagnosis of liposarcoma. A lipoblast is capable to produce and accumulate non–membrane-bound lipid within its cytoplasm. The most important morphologic features in diagnosing the liposarcoma are the demarcated cytoplasmic lipid that shifts the indentations in an irregular hyperchromatic nucleus and the characteristic scalloping of the nuclear membrane.

Well-differentiated liposarcomas usually contain a predominance of mature fat cells with relatively few, widely scattered lipoblasts. In the sclerosing subtype of a well-differentiated liposarcoma, collagen fibrils that encircle fat cells and lipoblasts make up a prominent part of the matrix.

Myxoid liposarcoma, the most common type, is diagnosed by the observation of a delicate plexiform capillary network that is associated with both primitive mesenchyme-like cells and a variable number of lipoblasts. In the round-cell type, lipoblasts are interspersed among sheets of poorly differentiated round cells.

Poorly differentiated pleomorphic liposarcoma is recognized by a mixture of bizarre, often multivacuolated lipoblasts and atypical stromal cells, many of which contain highly abnormal mitotic figures. Hemorrhagic and necrotic areas are common. Lipoblasts are present [12].

Leyomiosarcoma

Leiomyosarcoma derives from smooth muscle tissue, Wolffian duct remnants or blood vessels, being the second most frequently primary retroperitoneal tumor. This type of sarcoma can grow and reachenormous sizes (>10 cm), being more frequently encountered in female patients, usually in the 5th or 6th decade of life. Histopathologically, it is characterized by large areas of cystic degeneration and necrosis, but calcification is uncommon. Immunohistochemistry (IHC) experimental tests have showed that the tumor cells were significantly stained by desmin and actin antibodies, with some variation in staining intensity in different tumor cells. Relatively frail vimentin staining has been observed, especially if it is compared with the intense vimentin - specific decoration of endothelial cells and fibroblasts. Leiomyosarcoma can manifest itself predominantly as extravascular (62%), intravascular (5%) in the retroperitoneum or it can have a combination of extra- and intravascular components (33%). At CT examination, small tumors are usually homogeneously solid, although large tumors have areas of necrosis and occasional hemorrhage.

Extremely rare, leiomyosarcoma can appear as a cystic tumor. The MRI highlights these tumors to have intermediate to low signal intensity on T1-weighted images and intermediate to high signal intensity on T2-weighted images, depending on the amount of necrosis. So in conclusion, the existence of necrosis in a retroperitoneal tumor, with contiguous involvement of a vessel, is suggestive for leiomyosarcoma. Distant metastases usually occur late in the course of the disease, the most common locations being the liver, the lungs and/or lymph nodes [1, 13].

Approximately 6% of these retroperitoneal tumors arise from the inferior vena cava (IVC) [1]. These tumors have a large extravascular component that makes it difficult to distinguish them from a secondary involvement of the IVC. The most commonly affected location is the segment between the diaphragm and the renal veins. Tumors involving the superior segment of the IVC (above the hepatic veins) may manifest with Budd-Chiari syndrome, those of the middle segment (between the hepatic and renal veins) manifest with right upper quadrant pain, discomfort, nephrotic syndrome, or arterial hypertension [14-17] and the tumors of the inferior segment of the IVC (below the renal veins) can manifest with pain and lower extremity edema [13]. The differential diagnosis includes benign thrombus, angiosarcoma and a tumor extending to the IVC from adjacent organs [13, 18]. Tumors that develop from the middle segment of the IVC seem to have a better prognosis than those that arise from other IVC segments [18].

Malignant Fibrous Histiocytoma

This type of tumor is the third most common retroperitoneal sarcoma, but overall is the most frequently sarcoma in the body [19]. Malignant histiocytoma derives from primitive mesenchymal elements and it is estimated that approximately 15% of these tumors appear in the retroperitoneum [1]. In terms of gender distribution is it reported that male patients have higher risks for developing this type of tumor (75% male patients versus 25% female patients), being discovered especially in the fifth decade of life. Imaging techniques are nonspecific and usually describe a large, intrusive and heterogeneously enhancing mass with large areas of necrosis and hemorrhage, with invasion of the nearby organs, like other pathologies look alike [20]. Different patterns of calcification can be seen in the peripheral areas of these tumors. A cystic variant with peripheral calcification has been reported. The presence of calcification may help to distinguish leiomyosarcoma from malignant fibrous histiocytoma [1].

Germ cell, sex cord, and stromal cell tumors

Primary extragonadal Germ Cell Tumors

Even though germ cell tumors are present commonly in the testes or ovaries, a slight percent of germ cell tumors arise from an extragonadal location. These tumors are supposed to appear from abnormal primordial germ cell remnants that are cause of: germ cells distributed physiologically to liver, bone marrow, and brain or faulty migration of germ cells from the yolk sac or endoderm to the urogenital ridge [21]. Before an analysis of primary extragonadal germ cell tumor is made, a metastasis should be excluded. Sometimes the primary gonadal tumor could not be detectable because tumor relapse has left only a scar, with asynchronous or synchronous metastasis. This type of tumors is more frequently found in men. From the histopathological point of view, these tumors are classified in nonseminomatous germ cell tumors or seminomas, which involve teratoma, yolk sac tumor, choriocarcinoma, mixed germ cell tumors, and embryonal carcinoma. Increased levels of the beta subunit of human chorionic gonadotropin (choriocarcinoma) and of alpha-fetoprotein (yolk sac tumors, embryonal carcinoma) may be found with laboratory tests [21].

Extragonadal germ cell tumors are frequently seen near the midline, especially between the T6 and S2 vertebrae, the retroperitoneum being the second most common site after the mediastinum, a midline mass being more evocative for a primary extragonadal germ cell tumor than of metastasis. At imaging, the data collected are nonspecific for primary extragonadal germ cell tumors. The imaging characteristics are similar to those of gonadal germ cell tumors. Seminoma is occasionally located in the retroperitoneum and it can be recognized as a lobulated, large, well-defined homogeneous solid mass with fibrous septa and ring-like or speckled calcification. Non-seminomatous germ cell tumors are illustrated as heterogeneous tumors with areas of necrosis, hemorrhage and heterogeneous enhancement. The tumors in the extragonadal sites have a worse prognosis than that of their gonadal counterparts [22].

Lymphoid and Hematologic Neoplasms

The most common retroperitoneal malignancy is represented by lymphoma that accounts for approximately 33% of the retroperitoneal malignancies [1].

Lymphoma can be generally categorized into non-Hodgkin lymphoma and Hodgkin lymphoma. Hodgkin lymphoma usually occurs in patients during their second and sixth decade of life, having a bimodal age of distribution, often involving the spleen and mediastinum, manifesting itself with limited disease. Non-Hodgkin lymphoma is manifested in the forth-seventh decade of life, often associating extranodal disease in the spleen, bowel or liver. It is estimated that paraaortic lymph nodes are affected in 55% of the patients with non-Hodgkin lymphoma, as well as in 25% of the patients with Hodgkin lymphoma. A retroperitoneal mass can be discovered in approximately 15% of the subjects with non-Hodgkin lymphoma. Mesenteric lymph nodes are also frequently involved in non-Hodgkin lymphoma [1, 2].

At CT, lymphoma is identified as a circumscribed homogeneous mass, with moderate homogeneous contrast enhancement, that disseminates between normal structures without compressing them. The IVC and aorta can be anteriorly modified, producing the imagistic sign called “floating aorta”. Necrosis and calcifications are exceptional before therapy [23]. According to literature approximately 23% of the non-Hodgkin lymphomas are heterogeneous and they cannot be differentiated from other primary retroperitoneal tumors on the basis of their enhancement characteristics alone.

Ureterohydronephrosis, with secondary urinary tract infections [24, 25] and IVC obstruction may be found [1].

Image-guided needle biopsy is a first-line investigation when facing such cases, being useful in the diagnosis of lymphoma present in the retroperitoneum, especially if we consider its simplicity, as well as its noninvasiveness, often sparing the patients from radical procedures. Lymphoma comprises a heterogeneous group of lymphoproliferative malignancies, with varying morphologic features depending on the specific subtype [26, 27]. The abnormal lymphocytes in the lymph node, bone marrow, or in extranodal sites can be small, cleaved or noncleaved, intermediate or large cells and they can have a follicular or diffuse pattern. In contrast to reactive follicular hyperplasia, lymphomas usually alter the lymph nodes architecture, the capsule being usually involved [26, 28].

However, needle biopsy encounters several limitations; in few cases, core needle biopsy offers an amount of normal tissue or tissue that has lost its normal architecture, making diagnosis impossible [28, 29].

Immunophenotypic analysis aids to determine neoplastic from reactive lymphoid infiltrates, nonlymphoid from lymphoid malignancies, and specific lymphoid neoplasms. Although bcl-2 expression differentiates reactive follicular hyperplasia from follicular lymphoma, bcl-1 expression strongly supports a diagnosis of mantle cell lymphoma. CD30 expression is also important for the identification of anaplastic large cell lymphoma and it can also be found in the majority of Hodgkin lymphomas. Lymphoma is treated with chemotherapy or radiation therapy [30]. Soft-tissue masses can persist after treatment due to fibrosis and cannot be dif¬ferentiated from viable tumors [31].

Cystic Neoplastic Masses

Retroperitoneal cysts are infrequent, these tumors rarely producing symptoms, usually these symptoms being related to the cysts location and size, as well as to their complications. Differential diagnosis should be made between retroperitoneal cysts and omental, mesenteric, splenic and enteric duplication cysts.

Serous Cystadenocarcinoma

Serous cystadenocarcinoma is a rare primary epithelial retroperitoneal tumor that develops through mucinous or serous metaplasia of retroperitoneal coelomic mesothelium, which is located along ovarian descents [32]. Other approach of expansion includes a supernumerary ovary, an enterogenous cyst and a teratoma. Serous cystadenocarcinoma is discovered in women with normal ovaries. Histopathologically, the mass is multicystic and encapsulated, full with serous fluid and extruding papillary nodules. Imaging techniques are nonspecific and display a defined cystic mass with solid intramural nodules. Increase of the wall and solid components may be found. Other important diagnostic characteristics include: an elevated carcinoembryonic antigen level in the serum andglandular epithelial cells at biopsy [32]. This type of neoplasia needs surgical excision with wide margins [33]. Other rarely primary retroperitoneal epithelial neoplasms are mucinous cystadenocarcinoma, borderline mucinous tumor and borderline serous tumor [32].

CONCLUSIONS

Retroperitoneal masses can appear from different tissues and are a heterogeneous group, including some rare neoplasms.

Histopathology, immunohistochemistry, imaging techniques and other diagnostic exams are valuable in the evaluation of the retroperitoneal masses, particularly in staging as well as in assessing the nearby invasion. Although for now a specific diagnosis may be difficult to determine due to a lack of diagnostic information, the identification of certain characteristic features, along with clinical and demographic information, may help in narrowing the differential diagnosis.

Primary thyroid lymphoma – case report

Remus C. Stoica[1], Alexandra T. Pasare[2], Razvan G. Curca[2], Andrei W. Anghel[1], Stefanel Vlad[3]

Abstract*: Introduction. Even though, primary thyroid lymphoma (PTL) is a rare thyroid malignancy and extranodal non-Hodgkin lymphoma, this type of disease should not be disgraced in order to achieve an early diagnosis and multimodal treatment.*

Materials and method. We selected for discussions a primary thyroid lymphoma patient with absent constitutional (B-type) symptoms, who undergoes a multidisciplinary approach of the disease, chemotherapy and radiotherapy. In this clinical case report a 84 yo male patient with stage IE diffuse large B-cell histological type (Ann Arbor staging) was treated using R-CHOP chemotherapy, followed by involved field radiotherapy, with an excellent treatment response and disease control.

Results and Discussion. Usually this type of extranodal non-Hodgkin lymphoma is present in the seventh decade of life, with males being affected earlier than females. One of the most common presentations of thyroid lymphoma is an enlarging neck mass and a history of Hashimoto's thyroiditis, which is the major risk factor. The most common PTL subtypes are diffuse large B-cell lymphoma (the most aggressive histological subtype, representing 70% of all PTLs) and MALT lymphoma (30% of the PTLs). Advances in both diagnosis and treatment in the last years have improved the early diagnosis and shortened the time for treatment implementation.

Keywords: *primary thyroid lymphoma; non-Hodgkin lymphoma; thyroid cancer; radiotherapy*

INTRODUCTION

Even though lymphoma is one of the most common hematological malignancies, primary thyroid lymphoma (PTL) is very rare and accounts for 0.5-5% of all thyroid malignancies and about 2% of extranodal lymphomas [1]. Chronic Hashimoto's thyroiditis it is one of the main risk factors known to increase incidence of this type of malignancies [2]. PTL is a rare extranodal lymphoma which is defined as lymphoma that involves just the thyroid or the thyroid and the regional lymph nodes, without metastasis to other areas at the time of diagnosis [3].

Treatment and prognosis varies according to history and clinical stage. Surgery, chemotherapy, radiotherapy or their combination are the treatment of choice in this particular type of Non-Hodgkin Lymphoma (LNH). Such a case, with PTL, is presented in this article [4].

CASE REPORT

An 84 years old man, known with Hashimoto's autoimmune thyroiditis, with no other relevant personal or family history, visits the oncology department for recent-onset gross neck mass, throat

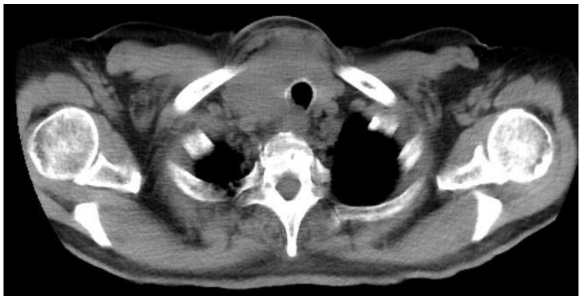
discomfort, dysphagia and hoarseness (noticed about 1 month before presentation). The patient had no fever, night sweats or weight loss. The physical examination reveals firm, immobile and painless mass descending in the anterior chest wall. Thyroid hormones at presentation revealed high antithyreoglobulin antibodies, an increased thyrotropin level and normal thyroxin. The ultrasound showed a macronodular goiter and chronic lymphocytic cells. On the CT examination of the head and neck region, showed an enlarged thyroid gland, with a nodular structure, starting from the hyoid cartilage and ending in the upper mediastinum (Figure 1). The endotracheal biopsy and immune histological analyses led to the diagnosis of a Non-Hodkin diffuse large B-cell lymphoma (DLBCL), CD20+, Ki-67>90%. A bone biopsy was requested for disease staging, which showed no evidence of neoplazic cells on the examined tissue. Also, the CT scan of thorax, abdomen and pelvis showed no other signs of evolution.

Figure 1 (explication in text)

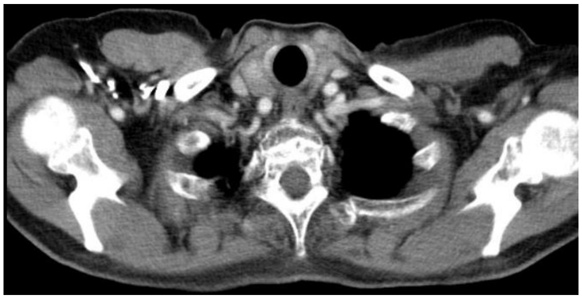


Regarding the fact that only the thyroid was involved (which is an extranodal site, on the same side of the diaphragm) and the fact that the patient had no B symptoms (fever, night sweats or weight loss), the stage of the disease, at the time of the diagnosis, was stage I AE.

After the diagnosis, the patient underwent 4 cycles of chemotherapy with R-CNOP chemotherapeutic protocol, i.e. rituximab (anti CD-20 antibody) 1400 mg, mitoxantrone 14 mg, cyclophosphamide 1350 mg, vincristine 2 mg and dexamethasone 16 mg. The treatment, after 4 cycles of chemotherapy, was stopped because of low tolerance. At the PET-CT scan, following chemotherapy was highlighted high metabolic activity in the right thyroid lobe.

Radiation therapy (RT) was recommended after chemotherapy. A total dose of 36 Gy (18 fractions, 2Gy/fraction) was administrated, using involved field technique to delineate the clinical target volume (CTV). For treatment preparation a fusion between PET-CT and planning CT-scan had to be used for accurate CTV delineation. Three months after radiotherapy, another PET-CT scan was made, to evaluate treatment response, showing low metabolic activity in the right thyroid lobe. The follow-up at 9 months post-chemoradiation was done using clinical examination and a CT scan, which showed a marked regression of the tumor mass (Figure 2).

Figure 2 (explication in text)



DISCUSSIONS

In general population this type of disease is rare, with an annual incidence rate of 2.1 persons per milion [6]. Also, it is known that PTL affects mainly women (5x times more common in women than men) between 50 and 80 years of age, whereas its incidence is low in individuals younger than 40 years of age [7].

We presented a patient with chronic lymphocytic thyroiditis (Hashimoto's thyroiditis), high levels of antithyroglobulin antibodies in different blood tests. These types of patients, with Hashimoto's disease, have a much higher risk of PTL than the general population. It has been presumed that abnormalities in immunity due to an approximately 20-year history of Hashimoto's disease increase the risk of developing PTL [8].

Clinical findings in our patient on presentation, made us consider an anaplastic carcinoma of the thyroid gland, because of the overlapping symptoms. After tumor and bone biopsy, the initial assumption was changed into primary thyroid B-cell lymphoma. The bone biopsy was made to exclude systemic involvement [9].

The current standard of care is chemotherapy followed by radiotherapy. The role of surgery has been diminished, because an aggressive debulking surgery would not have a more successful response over chemo-radiotherapy [10]. The recommended treatment was 6 cycles of R-CHOP followed by adjuvant RT [5]. In our case it was used R-CNOP chemotherapy because of mitoxantrones lower cardiotoxicity than doxorubicin, but with the same therapeutic outcome as the R-CHOP scheme [11]. RT treatment plan was realized by applying involved field radiotherapy technique, which included in the CTV the whole thyroid gland. A total dose of 36 Gy (2 Gy/fraction, 18 fractions) was administered at the end [7, 12].

An excellent prognosis for early stage PTL (stage IE and stage IIE) is achieved with proper modern treatment management and a multidisciplinary approach. A 5-year survival rate of 87.5% has been observed in patients with DLBCL type. Using modern treatment (combination of chemotherapy plus rituximab agent and radiotherapy), a good response is observed in this type of patients [7].

Principles of antimicrobial therapy in urosepsis: an approach from the perspective of the infectious diseases physician

Valeriu Gheorghiță[1,2], Costi Ghiațău[2], Filip A. Ariciu[2], Ion Ștefan[2,3], Adelina M. Radu[4]

Abstract*: Background: This topic is aimed to review the treatment approach in adult patients diagnosed with urosespsis, in order to decrease mortality and to maximize the outcome of the antibiotic stewardship efforts.*

Methods: We present an approach of antibiotic therapy in urosepsis from an infectious diseases physician perspective, based on the recently published data integrating the epidemiology of the urinary tract infections in a multidisciplinary hospital from Romania.

Results: The principles of therapy in urosepsis should have five goals, but not limited to rapid diagnosis, specific intensive care unit treatment, obtaining urine and blood cultures, anti-infective treatment and identifying and correction of underlying risk factors. Due to the higher prognostic value, the antimicrobial therapy in urosepsis should consist in "two steps" regimen: initial antimicrobial therapy, based on "empirical" approach for the first 48 - 72 hours and directed or "definitive" antimicrobial therapy adapted to the susceptibility profile of the isolated pathogens, the penetration into the urinary tract and the patient clinical response. Clinicians should be aware of the different antibiotic susceptibility profile of the bacteria from the hospital compared to the community. Thus, the initial choice of antimicrobial agents depends on several criteria like the severity of illness and the risk factors for multidrug resistant pathogens: the immune status of the patient (age, debilitating chronic illnesses, immunosuppressive treatment or uncontrolled malignancies), broad-spectrum antimicrobial use and health care environment exposures in the previous 3 to 6 months, susceptibility of prior urinary isolates, and local community resistance prevalence of bacteria.

Conclusions: Our important messages highlighted the need of a holistic approach of urosepsis, in a multidisciplinary team, with integration of risk factors for AMR, focusing on the first phase of antibiotic treatment as the main driven of the survival rate.

Keywords: *urosepsis, antimicrobial therapy, infectious diseases, antibiotic resistance*

INTRODUCTION

In about 30% of the sepsis cases, the underlying condition is related to the urinary tract infections (UTIs). The main risk factors are obstructive uropathies and most frequently, urosepsis develops in the context of health care–associated (HCA) UTIs [1]. The prognosis of urosepsis is more favorable compared to that of sepsis in general, with a mortality rate about 20–40% for severe cases. Unlike etiology in all-cause sepsis, dominated by gram-positive bacteria (GPB), the most common pathogens isolated

in urinary sepsis are gram-negative bacteria (GNB) [2]. In March 2018, the Centers for Disease Control and Prevention released the "Hospital Toolkit for Adult Sepsis Surveillance", a guidance useful for hospitals to identify sepsis outcomes and evaluate the effectiveness of sepsis prevention efforts [3].

In our perspective, one of the main causes of failure to antibiotic treatment in sepsis is related to the antimicrobial resistance (AMR) and inadequate spectrum of the prescribed antibiotics at the beginning. Therefore, this topic aims to review the treatment approach in adult septic patients with acute complicated UTIs, in order to decrease mortality and to follow the antibiotic stewardship recommendations.

ETIOLOGY AND SUSCEPTIBILITY OF ISOLATED STRAINS

Worldwide, the etiology of urosepsis is dominated by enterobacteriaceae, with Escherichia coli (E. coli) accounting for about 52% of the cases, followed by Klebsiella species (spp), Pseudomonas aeruginosa, Enterobacter spp and GPB, such as enterococci (5%) [4]. In 2017, among the strains isolated from the urology department of our Romanian tertiary hospital, E. coli was encountered in 59.2% of all cases of UTIs, followed by other GNB like Klebsiella pneumoniae (K. pneumoniae) [unpublished data].

It has been reported that the resistance rates of pathogens in urosepsis are higher than 10% for almost all antibiotics. The European Antimicrobial Resistance Surveillance Network for 2016 showed that more than half (58.6%) of the E. coli isolates were resistant to at least one of the antimicrobial groups under regular surveillance (aminopenicillins, fluoroquinolones, third-generation cephalosporins, aminoglycosides and carbapenems) [5].

According to the European Centre for Disease Prevention and Control, the level of E. coli resistance to carbapenems remained rare in 2016 (< 0.1%), with a national percentage ranging from 0% to 1%, meanwhile for K. pneumoniae, data showed large differences, ranging from 0% to 66.9% [6]. Carbapenem-resistant enterobacteriaceae (CRE) represents a significant threat to patients and healthcare systems in all European countries, being associated with high mortality, especially due to the delay in administration of effective treatment and limited treatment options [6]. Despite the fact that in 2016 the E. coli carbapenem resistance level in Romania has dropped from 1.9% to 1%, the reported rates of AMR are very high and rising in comparison to other European countries [7].

MANAGEMENT

In the management of septic patients, we must consider that sepsis is a life threatening condition with a directly dependent prognosis on the timeliness and accuracy of therapeutic intervention. In the latest update of the Surviving Sepsis Campaign (SSC) bundle from 2018, the most important change of the 2016 guidelines was that the 3-h and 6-h bundles have been combined into a single "hour-1 bundle" [8]. Clinicians should initiate antibiotic treatment immediately, especially in patients with hypotension, rather than waiting and extending resuscitation measures. Other measures such as obtaining blood samples, urine and blood cultures, administration of fluids and antibiotics, should all begin immediately [8].

The principles of therapy in urosepsis should follow five rules [9]. First of all, we have to establish a rapid diagnosis based on clinical and paraclinical tests: classical symptoms (dysuria, frequent urges to urinate, flank pain and/or costovertebral angle tenderness, fever, chills, pyuria), quick Sepsis Related Organ Failure Assessment score (qSOFA), biomarkers of sepsis and imaging findings [9].

In addition, a specific intensive care unit (ICU) treatment should be start with fluid replacement, supportive and adjunctive therapy as needed [9]. Obtaining urine and blood cultures prior to antibiotic administration represent another important rule [9].

On the other hand, initiation of antibiotic treatment must be adapted to the patient profile (usually broad spectrum antibiotics) after the quick assessment by the clinician and/or infectious diseases specialist [9]. The last but not least rule is addressed to identification and correction of risk factors (calculus, obstruction, renal or perinephric abscess) by the urologist [9].

ANTIBIOTIC TREATMENT

Broad-spectrum antibiotic therapy aiming to cover all likely pathogens should be started immediately, ideally in the first hour. Data from the literature have shown an association between the rapid administration of antibiotics and improved survival in patients with sepsis. Initiation of empiric antibiotic treatment within the first hour of hypotension is associated with a survival rate of about 80% [10]. Each additional hour of delay was found to decrease the survival rate by 7.6% [10].

The initial choice of antimicrobial agents depends on several criteria like the severity of illness and the risk factors for multidrug resistant pathogens: the immune status of the patient (age, debilitating chronic illnesses, immunosuppressive treatment or uncontrolled malignancies), broad-spectrum antimicrobial use and health care environment exposures in the previous 3 to 6 months, susceptibility of prior urinary isolates, and local community resistance prevalence of bacteria. Clinicians should be aware of the different antibiotic susceptibility profile of the bacteria from the hospital compared to the community. Therefore, an accurate classification of the UTIs according to the place of acquisition of the infection is mandatory. There have been defined two major categories of infections comprising of community-acquired (CA) UTIs or health-care associated (HCA) UTIs with the following scenarios: community onset HCA UTIs or hospital onset HCA UTIs. In CA-UTIs, the possible pathogens are limited usually to susceptible enterobacteriaceae, ampicillin-susceptible Enteroccous faecalis or Staphylococcus saprophyticus. In HCA UTIs, in general we are dealing with resistant strains of bacteria such as extended spectrum beta-lactamases (ESBL)-producing enterobacteriaceae or CRE. It has been shown that inappropriate antibiotic treatment in critically ill patients was associated with decreasing in survival rate of at least 5 times in septic shock [11].

Table 1. Choice of antibiotic therapy in urosepsis

"Empirical" phase of antimicrobial therapy *(combination therapy (ß-lactam antibiotics plus the second antimicrobial agent) is preferred especially in critically ill patients with high risk of death*		
Community-acquired UTIs[#] [#] *in some regions the risk of ESBL enterobacteriaceae has to be considered also in community-acquired UTIs*	**Health-care associated UTIs**	
	without risk of non-fermenting GNB or hemodynamically stable patient	*risk of non-fermenting GNB or hemodynamically unstable patient*
Aminopenicillins +/- beta lactamase inhibitor (BLI) (Amoxicilin/ clavulanate) 3rd generation cephalosporins (e.g. Ceftriaxone) Fluoroquinolones (e.g. Ciprofloxacin, Levofloxacin) Aminoglycosides (e.g. gentamicin)	Carbapenems (e.g. Ertapenem) Ureidopenicillin plus BLI (e.g. Piperacillin/tazobactam) Aminoglycosides (e.g. Gentamicin, Amikacin, Netilmicin, Tobramycin) Glycopeptides (e.g. Vancomycin)	Carbapenems (e.g. Imipenem, Meropenem, Doripenem) Carbapenems plus BLI (e.g. Meropenem/vaborbactam) Ceftolozane/Tazobactam Ceftazidime/Avibactam Monobactams (Aztreonam) Colistin Glycopeptides (e.g. Vancomycin) Aminoglycosides (e.g. Gentamicin, Amikacin, Netilmicin, Tobramycin)
"Directed" phase of antimicrobial therapy[±,¥]		

[±] *according to the antibiotic susceptibility profile of the detected pathogens*

[¥] *monotherapy is preferred (exception of critically ill patients with high risk of death and infections with CRE)*

The antimicrobial therapy in urosepsis consists in "two steps" regimen:

a) Initial antimicrobial therapy, based on "empirical" approach, should starts ideally, after obtaining blood and urine cultures, during the first hour of the patient presentation in the emergency room or after the diagnosis of urosepis in case of hospitalized patients. Due to the prognostic value of this treatment phase, as a general rule, the broad-spectrum antibiotics with good penetration into the urinary tract are preferred for the first 48-72 h [8];

b) Directed or "definitive" antimicrobial therapy represent an adaptation of the initial regimen (e.g. de-escalation) according to the antibiotic susceptibility profile of the isolated pathogen, taking into account the clinical evolution of the patient [8]. The duration of definitive therapy should have a minimum duration with maximum efficiency, usually between 10 to 14 days [2];

Based on our clinical experience and the evidence base medicine, we present a personal approach, not validated in clinical trials, regarding the choice of antibiotic therapy in urosepsis (Table 1).

In addition to antimicrobial therapy, an underlying condition such as urinary obstruction, anatomical or functional urinary tract abnormalities (neurogenic bladder, bladder catheters, nephrostomy tubes, and ureteral stents), should be rapidly identified and managed [12]. One of the important issues is related to the appropriate collection of the urine sample in case of urinary tract obstruction. In case of kidney drainage (e.g. percutaneous nephrostomy) we must collect also the urine from the inserted tube in addition to the usual urine sample.

ASSESSMENT OF TREATMENT RESPONSE

Usually, symptoms improve rapidly when antimicrobial treatment is effective, but the fever can persist at least 3 days despite the appropriate antibiotic treatment. The response to treatment is assessed by the following criteria: clinical (fever remission), biological (decreasing levels of inflammatory markers, sepsis biomarkers, alleviating organ dysfunction) and bacteriological (negative urine and blood cultures). In the PRORATA trial, a multicentre randomized controlled trial, it has been evaluated the use of procalcitonin (PCT) to reduce the patient's exposure to antibiotics in ICU. It has been shown that a strategy consisting in measurement of PCT concentration on a daily base allowed for a reduction of antibiotic consumption in ICU [13]. Also, other studies have been proposed a PCT-based algorithm for starting, continuing or stopping antibiotics in patients with sepsis in the ICU [14]. A Swiss randomized controlled trial showed that an algorithm based on PCT concentration and quantitative pyuria measurements, significantly reduces antibiotic exposure, with about 30%, without apparent negative effects on clinical outcomes [15]. In case of persistent or worsening symptoms after 72 hours of appropriate antimicrobial therapy, an additional evaluation is required in order to identify potential factors that might interfere with the favorable clinical outcome. Dosing reevaluation, especially for aminoglycosides and glycopeptides, surgical drainage of the new abscesses, assessment of the inserted tube position and permeability, repeating urine and blood cultures and readjusting treatment to the antibiotic susceptibility profile of other isolated pathogens, should be considered.

CONCLUSIONS

Our important messages highlighted the need of a holistic approach in urosepsis, provided by a multidisciplinary team, with integration of risk factors for AMR, focusing on the first phase of antibiotic treatment as the main driven of the survival rate. The new sepsis "hour-1 bundle" and the principles of antimicrobial therapy should be followed in all emergency departments as a clinical tool intended to improve the general prognosis in urosepsis.

Prioritisation in delivering health services: A military health system example

Ünal Demirtaş[1]

Abstract: *Objectives: The aim of this study is to use of available resources effectively and efficiently, to determine the situation of recource allocation, priority setting and to offer an insight into future planning in delivery of health services in Turkish Armed Forces (TAF).*

Study Design: This study was conducted using qualitative focus group method and it is a descriptive and qualitative study. Questions to be asked in the focus group discussions, the location and the time of discussions and the participants was determined by review of the literature.

Methods: Focus group interviews lasted between approximately 90-120 minutes, respectively, to each focus group, 9 chief phsycians, 13 doctors /dentists, 6 nurses, 8 health noncommissioned officers, 7 officers, 6 noncommissioned officers and 6 health administrators were attended.

Results: The result of focus group discussions; priority settings in military health services must be done and to preventive health care would be prioritised. The military hospitals in Internal Security Operation Area should be strengthened in terms of medical personnel and medical supplies and be full-fledged hospital. There was found that secondary care should be met from civilian hospitals in the other regions.

Conclusion: It is evaluated that the study will be contributed to set of priorities in TAF military health services take the investments in the public or private health sectors and operational requirements into consideration, the studies carried out by TAF Medical Command in order to restructure of the military hospitals, to be employed the recources allocated for health services and health personnel graduated from Gulhane Military Medical Academy such as physicians, health noncommissioned officer and nurses in real requirement positions.

Keywords: *Military hospital, prioritisation, primary health services, focus group, health personnel*

INTRODUCTION

Health services have great importance in protecting human health and according to the World Health Organization, they include all services necessary for diagnosis and treatment of all diseases, maintenance and improvement of health [1].

Primary purpose of health services is to protect the society from diseases and to ensure all individuals are healthy during their lifetimes within the scope of preventive health services; when it is not possible, to provide diagnosis and treatment services which are the secondary purpose of health services; and the third purpose is to give rehabilitation services to individuals who have not fully recovered [2].

Facilitating the access to health services, improving the scope and quality depend on resources such as money, personnel, material and medicine.

During the last 50 years, GPD expenditure on health in OECD countries has increased from 3.7% to 9.4%. Growth in health expenditures has nearly exceeded the economic growth

---

Corresponding author: Ünal Demirtaş
drunalde@gmail.com

nearly in all OECD countries in the last 15 years. Since current resources are insufficient compared to this growth and it is difficult to meet all health needs in an optimum level with current means, it is concluded that health services need to be limited and prioritization concepts in health services have begun to be studied [3].

Prioritisation in health services is a complicated decision process which includes many dynamics and decision-makers such as plans/plannings regarding which services, regions, programs, hospitals, patients or diseases the resources allocated to health service should be divided into primarily.

Prioritisation in health services is realized by receiving opinions of all sides and analysing data regarding service demands. These are findings regarding politicians and health managers, service providers (doctor and other health personnel), service recipients (society) and cost and efficiency of health needs and proper responses/treatments [4].

Methods such as public opinion survey, opinion researches, public meetings, focus group studies are used to determine the priorities in health services.

Prioritisation and resource allocation in health service can be used in many criteria such as respect for humans, necessity, individual responsibility, efficiency, the number of persons affected as well as fundamental criteria such as lifesaving, cost- effectiveness, cost- benefit and equality [5].

Determination of priority studies have been realized in many countries for many years. National Health Accounts (NHA) and National Burden of Disease (NBD) studies were realized for prioritisation in health services in Turkey [6], but no study regarding the prioritisation in national and international military health services has been found.

Military health services include controls for compatibility and suitability to the task and periodical or mandatory controls, health certificate control, prevention and removal of medical threats, discharge, treatment, health logistics, blood services and other needs with regards to military health [7].

The aim of military health system is to provide sustainability for soldiers to be healthy, prevent the weakening of combat power due to epidemics, discharging the wounded in time and successfully and saving the limbs and life of the injured. In short, it is to increase the desire and confidence for warfare of each soldier by facilitating well-coordinated and not-failing health system, keeping militant power fit [8].

Purpose of this study is to determine priorities regarding health services by taking military operational requirements and features into consideration, shedding light on studies conducted with regards to restructure of military hospitals, revealing data to take a good turn in terms of resources allocated for armed services. Also, it is to contribute to the employment of military health personnel, especially doctors, medical non-commissioned officers and nurses, in the areas where there is actual need.

MATERIALS AND METHODS

Study of prioritisation in delivering health services is realized through focus group meeting which is a qualitative method. Focus group meetings were realized from September 2014 to April 2015. The universe of this study consists of sides of health services which are service providers (doctors, nurses and medical non-commissioned officers), service recipients (commissioned officers, non-commissioned officers, specialized sergeants/privates and their families) and health managers (hospital chief surgeons, health administrators and headquarters planners). Participants are selected from chief surgeons and hospital administrators who work in different military hospitals; doctors, nurses and medical non-commissioned soldiers who have worked in different garrisons and have experience in terms of troop and headquarters, willing personnel of commissioned officers and non-commissioned officers who received health service from primary care and secondary care health organisations – who accept to participate to focus group meeting.

Focus group meetings were realized in four stages in this study. In the first stage, the subject of prioritisation in health services is presented through a wide scale literature review. In the second stage whom to be interviewed was decided. Groups who participated to the focus group meeting and their numbers are presented in Table 1.

After reviewing the literature, the questions to be asked in focus group meetings were prepared with contributions from the Department of Military Health Services, the Department of Biostatistics and Epidemiology faculty members who have worked in different positions including administration in different levels of health system. Which titles were to be used and which questions to be asked in which order during the meeting were determined beforehand, the questions were prepared by abstaining from directing the interviewee.

In the third stage, the place and time of the meeting was determined. Meetings were minimum 60 minutes and maximum 120 minutes. 9 chief surgeons, 6 doctors, 6 nurses, 8 medical non-commissioned officers, 7 commissioned officers, 6 non-commissioned officers and 7 doctors/dentists participated to the meeting, respectively.

Table 1. Focus groups and number of participants in group consultation.

Status		Female		Male		Total	
		N	*%*	*N*	*%*	*N*	*%*
Healthcare Providers	Chief Surgeon	0	0	9	100	9	100
	Administrative Chief	2	33.0	6	67.0	8	100
	Medical/Dentist Officer	2	15.3	11	84.7	13	100
	Nurse	7	100	0	0	7	100
	Health Non-commissioned Officer	0	0	8	100	8	100
	Total	**11**		**34**		**45**	**100**
Healthcare Takers	Officer	0	0	7	100	7	100
	Non-commissioned Officer	0	0	6	100	6	100
	Total	**0**	**0**	**13**	**100**	**13**	**100**

In the final stage, the meeting was summarised, content analysis was performed on the acquired data and the meeting results were presented. Data acquired in this study is reviewed and interpreted by way of content analysis method, researchers compared data acquired from each focus group with other focus groups. Opposing and similar views are tried to be distinguished by benefitting from the perspective of each group meeting.

FINDINGS

Distribution of participants who participated to focus group meetings by force are presented in Table 2 and Table 3.

Table 2. Distribution of participants who provide health service by force (*there is no force separation regarding nurses*).

Status	Land Forces		Naval Forces		Air Forces		Gendarmerie		Total	
	N	*%*	*N*	*%*	*N*	*%*	*N*	*%*	*N*	*%*

Total	8	61.8	1	7.6	2	15.3	2	15.3	13	100

When the answers of participants are reviewed in focus group meetings, most participants stated that there is “a requirement for prioritization” to be able to present available resources and means in an effective and efficient way in terms of delivering health service, 1 of the nurses and 2 participants who receive health service stated that “all services must be provided without any prioritization”. Chief surgeons stated health care needs of armed forces as prioritization criteria; administrators and doctors stated operational requirements, civil health care means, cost-effectiveness status; nurses stated regional needs; medical non-commissioned officers stated regional needs, disease burden, frequent diseases whereas service recipients put emphasis on efficiency and cost-effectiveness.

When asked who should play a role in prioritization, people who provide healthcare service stated that especially doctors should play a role, opinions of those who receive service should be obtained, also opinions of patients who receive healthcare service and their families as service recipients must be received and they also stated that opinions of health personnel are important. Hospital administrators stated that the prioritization is needed to be realized according to operational requirements and opinions of generals who decide the operation are also needed to be received. A participant in the service recipient group stated that prioritization should be done according to data in the database by establishing a council for health science.

When asked if preventive health service, diagnosis-treatment services or rehabilitation services should be prioritized in terms of health care delivery of armed forces, health care providers stated their opinions that “preventive health service” and “primary health service delivered within unit” should be at the forefront by taking operational requirements into consideration since armed forces personnel mostly consist of able-bodied, young men and health service is given to a group healthier compared to the society. The opinion that duty of armed forces is to deliver primary health service and secondary and tertiary health are possible to receive from civil health organisations is stated especially by doctors and medical non-commissioned officers. Nurses who mostly work in hospitals and healthcare recipients stated that diagnosis-treatment services should be prioritized.

When the current structure of military hospitals is considered, chief surgeons stated that the most suitable thing is “to reduce the number of military hospitals and turn them into a general structure in terms personnel and medical devices” and to enable the existence of military hospitals only in the regions where there are operations against terrorism and “to enable other regions to receive secondary health service from civil hospitals”. Hospital administrators stated that the hospitals are currently inadequate and they are in no state to compete with civil health organisations in terms of service quality and delivered healthcare. Doctors, nurses and medical non-commissioned officers stated that actions should be in accordance with operational requirement, thus military hospitals outside of the region where there are operations against terrorism should be closed since secondary health service can be received from civil hospitals and military hospitals in the regions where operations against terrorism are realized should be fully-organised and in a level enough to compete with civil hospitals. Service recipients pointed out that military hospitals are not currently cost efficient and there is no high-quality health service in these hospitals, they also stated that there are only need to be military hospitals in the regions where operations against terrorism are realised so as to provide high-quality health service.

When asked which areas of expertise should be available in military hospitals, chief surgeons stated that “psychiatrists are essential” due to the increase in the number of personnel and specialized sergeants/privates who have psychological problems in the recent period, they also stated that there is a need for branches such as orthopaedics, general surgery, anaesthesia for operations; administrators presented their opinions that there should be evaluations specific to the regions, there is a need especially for psychiatry, emergency medicine, surgical branches and anaesthetists; doctors/dentists and nurses stated that there is a need for internal medicine, psychiatry, emergency medicine, anaesthesia and surgical branches; medical non-commissioned officers stated that there is no need for gynaecology and obstetrics and paediatrics, instead there should be surgical branches; some service recipients stated that all branches should be available and the others stated that there should be branches that can treat the wounded personnel.

RESULTS

When studies on this subject realized in countries such as USA, England, Germany, Holland and Sweden, it is determined that a basic benefit package is created to provide a balance between limited health resources and healthcare needs, to prevent parameters such as treatment costs, medicine and surgery expenses within the scope of general health insurance from imposing an excessive burden on national economy. Committees are formed to determine health services which are to be included in basic benefit packages. These committees consist of the representatives of healthcare providers (such as doctors, nurses) and healthcare recipients (society). Even though these committees differ in each country, they prepare guides in which priorities in delivering health services are determined by meeting with people from all levels of society and taking health data of countries into consideration. Whether disease-treatment (medicine, surgery etc.) expenses are to be covered by health insurances is decided according to these guides. Within this framework, studies such as International Health Accounts Household Health Expenses and Disease Burden Projects are realized in our country in the recent time.

Military health services are primary health services provided especially for operation. It is determined by all participants in the focus group meetings that primary health service should be prioritized. It is pointed out in the focus group meetings that there must be doctors and assistant health personnel in primary health organisations; it is not enough to have only health personnel and laboratory facilities and medical devices and materials should be re-enforced. Hospital administrators and doctor's point to the increase in the number of personnel and specialized sergeants/privates who have psychological problems in the recent years in troops, psychological counselling and guidance services which are mostly given by reserve officers could be more efficient if they are provided by regular personnel or civil psychologists.

In the studies realized by Wiseman and Rosén, transparency, equality, justice, efficiency, responsiveness of health system and health personnel's approach towards patients are stated as priority determination criteria in health services. In the study realized by Mamas, priority determination criteria in health services is stated as maintaining trust and accountability between patients and doctors and establishing patient-centered approach [9, 10, 11]. In some studies, criteria are determined as benefit of patient, cost effectiveness and severity of disease [12, 13]. In the PHD thesis by M. Top, the principles of equality, health need, cost- effectiveness are placed near the top [5]. In this study, prioritization criteria are listed as operational requirements of the region, status of civil health facilities in the garrison, benefit of patient and cost-effectiveness.

Parties who are required to take part in delivering health service are stated as doctors, patients and their families, respectively, by the doctors and as patients and their families, doctors and health authorities, respectively, by the patients who receive service in a study realized in Greece. Both groups stated that politicians should play no part [11]. In the study realized by Wiseman and others, it is stated that doctors, health service administrators and patients and their families should especially take part in determination of priorities [9]. In the studies realized by Bowling and Kneeshaw, the result was that doctors, local health authorities and public should be a great part of the prioritization studies [11]. In harmony with the literature, the opinion regarding health personnel and especially doctors is stated by service providers whereas service recipients had the opinion with regards to patients and their families and doctors in this study.

When military hospitals are evaluated according to their current state, it is seen that there are no specialists in many branches of many hospitals and there is only one doctor when there is a specialist in a branch. All participants who participated to the focus group meeting stated that secondary health service delivered in many military hospitals fall behind of civil health services and it would be suitable if military hospitals outside of the region where there are operations against terrorism should be closed and secondary health service is received from civil hospitals. It is emphasised that military hospitals in operation areas where fights against terrorism happen should be fully-organised with sufficient personnel, medical device and equipment and can provide service for 24 hours in a day with ambulance helicopters and health teams. The fact that many military hospitals are currently in an idle state and they can only provide service as polyclinics, the number of in-patients and surgeries are very low is exemplified. There are similar problems in the United States of America. Existence of military hospitals and how efficient and effective they are in their current state have become highly questionable. Pentagon military health administrations state that primary mission of hospitals is military needs, doctors and nurses must develop their abilities for combat requirements. Two thirds of USA Military Hospitals treated 30 or less patients daily in 2013 and less than one-third of them treated as many patients as civil hospitals treated. Nine hospitals treated 10 or less patients [14]. The military worked in more than half of domestic hospital network until today. Pentagon analysts suggested that 15 of 25 hospitals are to be reduced, but the list has been reduced to eight due to complaints by Land, Naval and Air Forces [15].

When criteria such as operational requirements of military hospitals, status of civil health organisations in the region are considered, it is stated that areas of expertise that are required to have in military hospitals first of all must be to meet the operational needs; afterwards, psychiatry, internal medicine and anaesthesia, surgical branches such as orthopaedics, general surgery are listed by the participants. Common opinion of all groups who participated to the focus group meeting is that there is no need for branches such as paediatrics, gynaecology and obstetrics in military hospitals in the regions where there are operations against terrorism and these services can be delivered by civil health organisations. When the literature is examined, it is seen that 66% of injuries happening in theater of operations are orthopaedics, 21% is general surgery, 6% are of head and neck injuries, 5% are of burn injuries [16]. In another study based on the experiences of English military health personnel got in Afghanistan, it is determined that 93 of 124 people who had been wounded in battle lost their lives because of injuries in upper thigh, inguen and pelvic. Most of the casualties are because of pelvic injuries (17). Almost 11% of 7,856 trauma patients who applied to English Role-3 Sahara Hospital in Afghanistan from 2003 to 2011 applied because of chest trauma and almost 14% of them lost their lives. Most of the wounded people whose systolic blood pressures were detected very low had head and abdominal injuries and cardiac arrest and they caused mortality [18]. In another study, 83% of 271 people who lost their lives because of war injuries died because of brain injuries. 80%

of 287 people who were potentially survivable, haemorrhage caused by major trauma caused mortality. When bleeding site was examined in these people, it is determined that 48% of bleeding happened in torso, 31% extremity and 21% neck, axilla and inguen [19]. In a study realized by Owens and others, extremity injuries in 1281 soldiers are examined and it is seen that 53% of them have penetrating soft tissue injury, 26% have fractures and these fractures are localized similarly in upper and lower extremities [20]. Of injuries except thoracic injuries of 258 patients treated for thoracic injuries happened with weapons with high kinetic energy between 1996 and 2005, 13% are intra-abdominal injuries, 5% are fractures, and 3.5% are major vascular injuries [21]. The most frequent injuries of patients who are brought to an emergency ward in a hospital in Turkey after getting injured in the civil war in Syria are extremity injuries, internal diseases; chest, abdominal and head injuries with similar rates and eye injuries, respectively [22].

In the light of this information, as stated by the participants, it is important to have specialists on surgical branches such as orthopaedics, general surgery, brain surgery, cardio-vascular surgery, thoracic surgery and branches such as anaesthesia, internal medicine, radiology to be able to treat the wounded people effectively and increase the motivation of the personnel in the military hospitals in the regions where there are operations against terrorism.

DISCUSSION

The following results are obtained through this study realized with focus group meetings to determine priorities in delivering health service to armed forces.

Almost all parties and participants who participated to the study pointed out the necessity for determining priority in military health system to use resources allocated to armed forces effectively and efficiently since resources are limit, requirements are many. While making prioritization, it is stated that criteria such as operational requirements, structure of civil health organisations in the region and military health organisations being utilized by personnel and their families is needed to be considered because of unique structure of armed forces.

As a result of focus group meetings, it is determined that the opinions of doctors especially are needed to be at the forefront during prioritisation as well as opinions of health personnel, hospital managers such as chief surgeon, assistant chief surgeon, hospital administrator, privates who receive service and civil patients.

It is emphasised that the priority of armed forces should be primary health services and preventive health services and primary health service is a must for armed forces. Considering regional features and operational requirements, it is common opinion of all parties that secondary health service can be received from civil health organisations. Health boards in military hospitals stated that specific health services such as health service for operational requirement must be focused on and it is more appropriate for rehabilitation services to continue as they are currently.

It is determined that military hospitals cannot be utilized in an efficient and effective way due to the fact that personnel and their families prefer civil health organisations, there is not sufficient specialists, medical devices and materials are lacking, physical conditions of hospitals are worse compared to civil hospitals, there are problems in logistics and the system responds to the needs very slowly.

The importance of providing efficient, correct and quick primary health service is emphasised. Within this scope, it is pointed out that there must be a doctor regarding primary service, but it is not enough only to have doctors, there should also be laboratory facilities which consist of complete blood, urine, roentgen devices and primary health services must be supported.

Recently, there is an increase in the number of personnel and specialized sergeants/privates who apply to Psychological Counselling and Guidance Centers and it is determined that to deliver more productive service to these patients, regular personnel or civil officers should work instead of reserve officers so that the service becomes more effective and efficient.

When military hospitals are evaluated according to their current state, it is seen that there are no specialists in many branches of many hospitals and there is only one doctor when there is a specialist in a branch, especially in the surrounding hospitals. Participants are in agreement regarding the fact that the military hospitals in the regions where there are operations against terrorism must be re-enforced and turned into hospitals which have a fully-organised structured and several doctors in each branch to continue delivering service, hospitals except this must be closed or turned into health centers suitable to the unit needs.

Parties that participated to the group meetings emphasised the importance of quick and efficient patient/wounded discharge regarding operations is emphasised. Afterwards, it is concluded that having an ambulance helicopter which have regular health personnel who provide service in accordance with 24-hour principle within military hospitals and having first aid and emergency medical technician working in units which take part in operations improve the efficiency of health services.

The following suggestions are developed in the light of these results:

Health system of armed forces is required to be restructured in a way that efficiency and economy criteria are taken into consideration, medical board processes specific to armed forces can be realized, diagnosis-treatment abilities and capacities focused on unit and operation needs, in accordance with national health legislation are increased without losing specific features and by re-evaluating vision, mission, current situation and the point the national health system has reached.

Health Services Policy Determination and Assessment Board should be organised to give scientific support to restructuring studies of Health System, one member from the Departments of Public Health, Military Health Services, General Surgery, Internal Medicine, Psychiatry, Infection Diseases and Family Medicine and Health Services Management and the Department of Epidemiology, 5 Chief Surgeons from Military Hospital and 3 general practitioners should be assigned.

Inpatient treatment facility and laboratory facilities which consist of complete blood, urine, roentgen devices should be provided especially for trainings units to deliver more efficient and effective primary health services and to make these services more suitable to unit needs.

For health board needs, regional hospitals, military hospitals outside of the region where there are operations against terrorism should be transformed into proper health centers, other military hospitals should be structured in accordance with the criteria of the Ministry of Health through personnel and medical device savings with this transformation.

As specialist quota is determined, planning should be made by considering operational requirements of armed forces, current status of staff in health board branches, especially branches such as general surgery, orthopaedics, anaesthesia, internal medicine, psychiatry, and radiology should be focused on.

When the fact that there is an increase in the number of personnel and specialized sergeants/privates who have psychological problems in the recent periods, regulations regarding regular personnel recruitment should be made to solve problems arising from conducting psychological counselling and guidance services in the troops especially with reserve officers.

Procedure and effectiveness of Basic Cardiopulmonary Resuscitation during the landing of an airplane: an exploratory study on military flights

Manuel Pardo Ríos[1,2], Sergio Nieto Caballero[1,2], Manuel R. Gracia Velilla[3], María del Lidón López Iborra[4], Juan J. Hernández Morante[1], Manuel Pons Claramonte[5], Esther Chicharro-Luna[6], Cristina Cerezo Espinosa[1]

Abstract: *Introduction: The incidence of cardiorespiratory arrest (CRA) in aircraft is estimated at one per 5-10 million flights. The early initiation of cardiopulmonary resuscitation (CPR) can double or quadruple survival rates after CRA, and is associated with a better prognosis in terms of decreased brain damage and better quality of life. The aim of the present study is to evaluate the effectiveness of basic CPR procedures carried out by the flight crew in a clinical simulation performed in a real environment, during the landing of a military training flight.*

Methodology: The clinical simulation was carried out with 20 members, grouped in ten pairs, of the Méndez Parada Military Parachuting School at the Alcantarilla Air Base (Murcia, Spain). At an altitude of approximately 1,100 feet, each pair simulated CPR on a Little Anne® manikin fitted with a SimPad® PLUS. The results obtained were recorded by SkillReporter ™.

Results: The mean duration of the procedure was approximately five minutes. During the flights, the compression depth achieved with CPR was correct in only six of the ten cases. In only one case was the "patient" checked for consciousness and respiration. In 50% of the simulations, the forehead-chin manoeuvre was not performed (i.e., the airway was not opened).

Conclusions: The lack of standard recommendations in current guidelines on CPR during aircraft landing may provoke discrepancies in the management of this critical situation and reduce the quality of the treatment provided.

Keywords: *cardiopulmonary resuscitation; aircraft; cardiac arrest; special environments; in-flight medical emergencies; landing medical emergencies*

INTRODUCTION

Although commercial aircraft are safe and passenger flight is one of the most widely used means of transport, the millions of persons carried, the fact that some will have pre-existing medical conditions and the long distances often flown all increase the chances of an in-flight emergency happening [1]. It has been estimated that cardiorespiratory arrests (CRA) occur in-flight once in every 5-10 million flights [2-4]. The prompt initiation of cardiopulmonary resuscitation (CPR) can double or quadruple the odds of survival after CRA, and is associated with a better prognosis in terms of decreased brain damage and better quality of life [5-7].

In-flight CPR is a challenging task. Some studies have suggested that the use of a mechanical resuscitation device produces a higher rate of chest compression than is obtained by standard basic life support. However, such devices are not always available [8]. The current guidelines of the American Heart Association (AHA) and the European Resuscitation Council (ERC) only offer general recommendations for in-flight CPR, without addressing aspects such as how to act if an emergency occurs during landing [9-11]. In the context of the armed forces, the role of critical care air transport teams and other trained personnel is essential for the safe transport of unstable patients and combat victims [12].

The aim of the present study is to evaluate the effectiveness

of the basic CPR procedure employed by the flight crew in a clinical simulation in an otherwise real environment, during the landing of a military training flight.

METHOD

The participants in this exploratory clinical simulation study were 20 members of the Méndez Parada Military Parachuting School at the Alcantarilla Air Base in Murcia (Spain), grouped into ten pairs of jump commanders. Ten clinical flight emergency simulations were created in a real environment during training for parachute jumps with automatic opening. This exercise took place in 2019, using T-12 Aviocar military aircraft (Figure 1A). The CRA simulation began five minutes before landing, at an altitude of approximately 1,100 feet (Figure 1B), when the crew was informed that a CRA had occurred. The simulation ended once the pilot had landed the aircraft and brought it to a halt. During this simulation, CPR was performed on a Little Anne® manikin fitted with a SimPad® PLUS and SkillReporter™, and wearing a helmet, TP2Z parachute, and RTP-26Z reserve (Figure 1C). The simulation was evaluated by two members of the research team (RG and LL), who also formed part of the crew during the training exercises.

Figure 1: Images of the CPR study context during landing. A: T-12 Aviocar military aircraft; B: Altimeter recording 1,100 feet, beside the Little Anne® manikin fitted with a SimPad® PLUS, a helmet, a TP2Z parachute and an RTP-26Z reserve; C: CPR simulation during flight and landing.

All participants gave prior signed informed consent and authorized the video recording and photographing of the simulation. All had basic life support training as part of their combat training and annual refresher courses.

RESULTS

Among the results obtained, the frequency of compressions per minute exceeded ERC recommendations [median ± IQR = 123 ± 32] and the mean depth (mm) was just within the recommended range [median ± IQR = 55.5 ± 11]. Figure 2 summarises the main data obtained in the quantitative evaluation of the quality of external chest compressions. The mean duration of the procedure was approximately five minutes (Figure 2a). The number, frequency and depth of compressions were similar in all the flights except number 7, in which the crew decided to secure the manikin; the difficulty involved in this process limited the effectiveness of their CPR actions (Figures 2b and 2d).

We also conducted a qualitative evaluation of CPR performance, by reference to the corresponding ERC guidelines [10]. Table 1 lists the results of this evaluation, quantifying the instances in which each aspect of CPR was performed correctly or otherwise. Notably, the depth of the compressions obtained was only correct in six of the ten cases considered.

DISCUSSION

Our qualitative assessment of the data on CPR performance reveals that chest compressions were performed better than ventilation. In the latter case, certain aspects were clearly open to improvement. This shortcoming has been reported previously, in the executive summary of the 2015 ERC guidelines [10]. In our case, the difference may have arisen from the fact that only basic life support was performed, that is, without the availability of material for the airway and within the confined space of an aircraft, which prevented good positioning for the mouth-to-mouth ventilation technique.

As recommended in Section 4 of the 2015 ERC guidelines ("Cardiac arrest in special circumstances"), the CPR was performed in a suitable place in our simulation exercises, within the limitations imposed by the characteristics of the aircraft9. Specifically, it was carried out in the middle of the fuselage, where there was most space, with the head of the simulated victim positioned towards the tail of the plane. Although the 2015 ERC guidelines do not indicate the most appropriate position for the victim's head, this question should be considered because the head is likely to suffer tilt variations during landing [10]. In each CPR simulation (in accordance with the ERC guidelines) the patient's chest was uncovered and, in this military tactical environment, the parachute and helmet attached to the manikin were also removed [10]. In one flight, the inappropriate positioning of the manikin reduced the quality of the compressions performed.

Figure 2: Quantitative characteristics of the external chest compressions performed. (a) duration of the session, in seconds [median ± IQR = 269 ± 68]; (b) number of compressions per session [median ± IQR = 265 ± 94]; (c) frequency of compressions per minute [median ± IQR = 123 ± 32]; (d) depth of compressions in millimetres [median ± IQR = 55.5 ± 11]. The solid line represents the median and the dashed lines represent the interval ± IQR.

Vertical position over the victim	4	6
Compression: 5-6 cm	6	4
30 compressions at 100-120/min	4	6
Hyperextension of the head	6	4
Pinch the nose	7	2*
Lips-mouth seal	6	-**
Insufflation for 1 second	9	1
Raise the chest	2	7*
Remove mouth, maintain forehead-chin manoeuvre and observe chest elevation	0	10
Maintain ventilation manoeuvres for no more than 5 seconds	10	0
30:2 ratio	10	0

** In one landing, this variable could not be determined by the evaluator; ** In four of the landings, this variable could not be determined by the evaluator.*

In six of the ten flights, CPR was suspended as the aircraft was landing, but the victim was secured in only four cases. Furthermore, the treatment team was not secured in any of the landings, although they did remain seated in six cases. Our review of the literature revealed no specific considerations on the question of safety precautions as the aircraft is landing [9].

In the present study, for which the simulations were conducted within military aircraft, the chest compressions were performed by crew members. Forti et al. [13] have observed that the use of mechanical chest compression devices should also be evaluated since these mechanisms can provide high-quality chest compressions in the confined space of an air ambulance. However, in the present case, this option was not feasible, as no such devices are incorporated in the aircraft considered. A positive factor in our study is that the military personnel who provided CPR attention all had basic life-support training and took annual refresher courses, thus complying with the recommendation that pilots and cabin personnel should be trained in emergency procedures [9].

As a proposal for improvement, the standard recommendations for CPR in aircraft, both in flight and during landing, should be more fully implemented. In this respect, we note that the current AHA and ERC guidelines lack specific recommendations for the treatment of cardiorespiratory arrest in aircraft.

CONCLUSION

In conclusion, we find that the absence of standardized recommendations in the current guidelines on CPR during aircraft landing can provoke discrepancies in the management of this situation and/or reduce the quality of the CPR operations performed. This outcome is due, in part, to the need to balance the safety of the patient against that of the treatment team (i.e., ensuring that everyone is properly secured when necessary and that CPR maneuvers are suspended in certain flight situations), or minimizing pauses in resuscitation, even if this endangers the physical safety of all involved.

Ethical approval and consent to participate

This study was approved by the Ethics Committee of the Catholic University of Murcia (UCAM) and by the Méndez Parada Military Parachuting School at the Alcantarilla Air Base (Murcia). All participants gave signed informed consent to take part in this study. All of the authors undertake to maintain data confidentiality and respect the rights of the participants. These undertakings are stipulated in the author responsibility document, the publication agreement, and the transfer of rights.

Psychological consequences of the Covid-19 pandemic. A study carried out on the psychiatric medical staff

Arina C. Trifu[1,2], Luminiţa Roşca[1]

Abstract: *Motivation for the choice of topic: The covid-19 pandemic has restructured the entire health care system. As systems of care were overwhelmed, many health professionals in related professional areas became increasingly involved in providing medical aid. The present paper aims to highlight a comparative analysis between two psychiatric wards of the same hospital, with qualified medical staff, with similar levels of competence, one of the wards caring for patients exclusively with major psychiatric pathologies, and the other patients with associated SARS-COV2 infection.*

The objective is to highlight links between different variables, such as motivation versus amotivation, anxiety and/or burnout, work experience, and resilience, all of which also relate to decisions to accept and provide quality medical care to this particular category of patients.

Methodology Application of specific questionnaires and scales on a group of 60 medical workers in two psychiatric wards, one of which was declared a ward working with psychiatric patients with covid.

Results: Resident doctors, then nurses, followed by hospital attendants, attending physicians and lastly psychologists, cope in descending order with professional stress related to covid-19 anxiety. This is high and correlates positively with depression and burn-out - which, in the case of young people, risks demotivating them to the point of destroying their future plans and the hope of successful professional self-esteem.

Conclusions: The covid-19 pandemic in a psychiatric hospital has raised anxieties even among medical staff, who have moved from somatic to psychiatric care over the years, and the comorbidity of mental illness and SARS-COV2 infection has raised particular problems. Among staff, anxiety, risk of depression, burnout, with depletion of compensatory resources have increased. Resilience calls for the use of mature defence mechanisms and professional experience protects against anxiety and burnout.

Keywords: *burnout; Covid-19 anxiety; stress; resilience; professional status*

INTRODUCTION

The particularity of the study lies in the fact that mental health workers are health professionals who routinely care for psychiatric patients, who are known to have certain characteristics such as: absence of insight into illness, loss of reality testing, productive phenomenology requiring particulars of supervision, suicidal risk, which may be amplified by somatic comorbidities. In other words, the group on which the research was carried out was a highly specific one - the motivation at work of employees in the "psy" area being a special one, involving dedication and training courses in the field, as well as an intrapsychic development developed over years, of a certain nature [1,2].

The research hypotheses were:

1) We assume there are statistically significant correlations between the psychological constructs analysed.

2) We can predict the level of employees' motivation according to the level of depression, resilience and healthcare experience.

[1] International Relations and European Studies PhD program, Faculty of History and Philosophy, "Babeş-Bolyai" University, Cluj-Napoca, Romania
[2] Military Medical Institute, 3-5 Military Medical Institute Str., Bucharest, Romania

3) We assume that there are statistically significant differences in levels of resilience and intrinsic motivation between employees in a Covid-support medical ward versus employees in a non-Covid medical ward.

4) The occupational status variable has a moderating effect on the relationship between resilience and motivation.

5) The occupational status variable has a moderating effect on the relationship between anxiety and burnout.

6) The healthcare experience variable has a moderating effect on the relationship between amotivation and fear of Covid [3].

METHODOLOGY

Participants

The research was carried out on 60 people, employees of the "Prof. Al. Obregia" Clinical Hospital of Psychiatry, Bucharest, working on two different wards, one declared by the hospital management as a non-Covid medical ward and one ward treating exclusively Covid positive patients. Participants filled in their status on the medical ward: consultant/ registrar (7%), resident doctor (12%), nurse (21%), hospital attendants (26.7%), clinical psychologist (6.7%). The mean age of the group was 39.83 (with SD = 10.47). The inclusion criterion for the study was the employment contract in the hospital and the participants' involvement in medical and psychological activities.

Sampling procedure

The research was carried out in an online environment. The study was carried out on participants employed at the "Prof. Alex. Obregia" Psychiatric Hospital in Bucharest and the completion of the instrument was done through Google forms. Participants were presented with a full description of the study and received written informed consent in accordance with the research standards for human subjects study and confidentiality of personal data was guaranteed. Participants had several professional occupations: consultants or registrars, medical residents, nurses, hospital attendants, clinand ical psychologists [4].

Instruments, measurements, variables

1) The DASS 21-R test [5], which consists of 21 questions with 4 response options on a 0-3 Likert scale (0 = "Did not fit me", 1 = "Fit me to a certain extent or sometimes", 2 = "Fit me quite a lot or quite often", 4 = "Fit me very much or most of the time"). The 21 questions measure 3 subscales (each with 7 items). Items 1, 2, 10, 13, 15, 18, 20 measure the Depression dimension. Items 4, 5, 8, 9, 12, 14, 21 measure the Anxiety dimension. The remaining items measure the Stress dimension. The final score is calculated by summing the items for each.

2) The Maslach Burnout Inventory (Schaufeli, Leiter, Maslach & Jackson, 1996) [6] is composed of 16 items with responses on a Likert scale from 0 to 6 (0 = "Never", 6 = "Daily"). The questionnaire consists of 3 subscales: Exhaustion, Cynicism and Professional Inefficiency The total score can also be calculated. A higher score means a higher burnout.

3) Connor-Davidson Resilience Scale (CD-RISC) [7], which contains 25 items with responses on a Likert scale from 0 to 4 (0 = "not at all true", 1 = "rarely true", 2 = "sometimes true", 3 = "often true", 4 = "always true"). The scale is based on how subjects have felt in the last month. The scale has scores between 0 and 100, with higher scores explaining higher levels of resilience.

4) Multidimensional Workplace Motivation Scale (MWMS) [8], which contains 19 items, with responses on a scale of 1 to 7 (1= "not at all", 2= "very little", 3= "a little", 4= "moderate", 5= "strong", 6= "very strong", 7= "total"). The scale measures 6 subscales: Amotivation, Social extrinsic motivation, Material extrinsic motivation, Introjection regulated motivation, Identification regulated motivation, Intrinsic motivation. A higher score is associated with a higher level of motivation.

5) Fear of COVID-19 scale [9] containing 7 items, with responses on a scale from 1 to 5 (1= "strongly disagree", 2= "disagree", 3= "neither agree nor disagree", 4= "agree", 5= "strongly agree"). Scoring is established according to the summative scale, with sums ranging from 7 to 35. The higher the score, the greater the fear of COVID-19.

In addition to the administered questionnaires, participants filled in factual data on: gender, age, education level, marital status, personal pathological history, health care experience, current work experience, education level, professional status [7].

Research design

The research took place in an online environment and was an observational, cross-sectional study. The database was processed in SPSS version 22, also using the PROCESS extension version 3.5. The variables we worked with were:

- Non-parametric variables: gender, education level, marital status, personal pathological history, education level, professional status;

- Parametric variables: Age, health care experience, current work experience, depression, anxiety, stress (measured with DASS 21), burnout, cynicism, professional inefficiency, total burnout (measured with Maslach Burnout Measurement

Inventory), resilience (measured with CD-RISC), amotivation, extrinsic social motivation, extrinsic material motivation, introjection regulated motivation, identification regulated motivation, intrinsic motivation (measured with MWMS), fear of COVID;

- Moderator variables: professional status, health care experience [10].

RESULTS

Descriptive analysis for the data collected is set out in Table 1.

Table 1: Descriptive analysis

	Minimum	Maximum	Mean	Std. Deviation	Skewness	Kurtosis
	Statistic	*Statistic*	*Statistic*	*Statistic*	*Statistic*	*Statistic*
Age	23.0	59.0	39.833	10.4770	-.010	-1.364
Health experience		43	11.12	10.183	.902	.252
Current experience		30	8.10	8.691	1.060	-.073
Depression	0	19	3.92	4.571	1.595	2.127
Anxiety	0	17	3.57	4.159	1.350	1.276
Stress	0	18	4.45	4.781	1.225	.768
Exhaustion	0	24	6.33	6.299	.793	-.373
Cynicism	0	22	5.20	5.713	1.106	.372
Professional inefficiency	0	27	6.90	7.498	.919	-.374
Burn-out	0	73	18.43	18.671	.954	-.076
Resilience	35	100	75.43	16.532	-.529	-.581
Amotivation	3	19	5.43	4.048	1.840	2.758
Extrinsic social motivation	3	21	9.42	5.782	.402	-1.014
Extrinsic material motivation	3	20	8.48	5.407	.394	-1.277
Introjection motivation	4	28	19.93	6.913	-.689	-.484
Identification motivation	3	21	17.33	4.501	-1.524	2.116
Intrinsic motivation	5	21	17.37	4.084	-1.147	.658
Motivation	33	111	77.97	19.749	-.566	-.346
Covid fear	7	26	12.83	4.705	.670	-.063

To operationalize the variables, the level of education that was noted among the participants was divided into three classes: postgraduate and bachelor studies (graduates of bachelor's, master's, and postgraduate programmes), high school and college of nursing (this included nurses who had graduated from the college of nursing or hospital attendants who had graduated from high school), and secondary school or 10-grade education (for those with less than 10 grades completed), as depicted in Table 2. The distribution by professional status is showed in Figure 1.

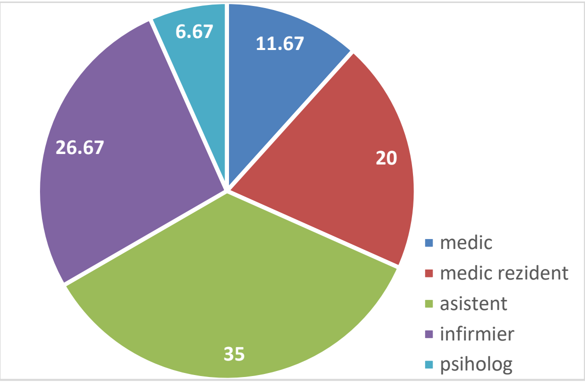
Table 2: Level of education

		Frequency	Percent
Valid	Bachelor studies and postgraduate	29	48,3
	High school and college of nursing	17	28,3
	High school	14	23,3
	Total	60	100,0

To test Hypothesis 1, which seeks to see if there are significant correlations between the psychological constructs analyzed on the group of subjects, we used Pearson correlation. Among the important correlations to mention, we list:

- There is a statistically significant negative correlation between experience in the health field (and experience in the current job, p=0.031, r=-0.279) and introjected motivation (p=0.018), with a weak correlation intensity (r=-0.305), which explains that as experience in the health field (implicitly the one from the current job) increases, the level of motivation through introspection decreases.

Figure 1: Distribution by professional status



- There are positive correlations of the depression scale with the exhaustion (r=0.744, strong to very strong intensity), cynicism (r=0.698, strong intensity), job inefficiency (r=0.644, strong intensity), burnout (r=0.732, strong intensity), amotivation (r=0.263, weak intensity), extrinsic social motivation (r=0.294, weak intensity), extrinsic material motivation (r=0.427, moderate intensity) scales.

- There are positive correlations of the anxiety scale with the exhaustion (r=0.703, strong intensity), cynicism (r=0.688, strong intensity), job inefficiency (r=0.688, strong intensity), burnout (r=0.724, strong intensity), amotivation (r=0.289, weak intensity), extrinsic material motivation (r=0.314, weak intensity) scales and a negative correlation with intrinsic motivation (r=-0. 28). These data explain that when anxiety levels increase, intrinsic motivation levels decrease.

- There is a positive correlation of stress level with all burnout scales (burnout, cynicism, job ineffectiveness), which denotes that when stress level increases, burnout level increases with its subscales. Stress also correlates positively with amotivation level (r=0.269, low intensity), which explains that when stress level increases, amotivation level increases.

- There is a positive correlation of fear from Covid level with anxiety level (r=0.368, low intensity) and stress level (r=0.263, low intensity), exhaustion level (r=0.384) and cynicism level (r=0.259), work inefficiency level (r=0.356, low to moderate intensity), burnout level (r=0.352, low to moderate intensity) and amotivation level (r=0.312, low intensity).

- Resilience level correlated negatively with the level of the scales: cynicism (r=-0.305), job inefficiency (r=-0.358), burnout (r=-0.322), amotivation (r=-0.327), identified motivation (r=-0.372). Level of resilience correlates positively with level of intrinsic motivation (0.603) [8].

To test Hypothesis 2, which sought to predict the level of motivation of healthcare employees according to predictor variables, we ran multiple linear regression analysis, where the criterion variable was motivation score (measured with MWMS). The motivation variable was included in the regression analysis as a dependent variable and several predictor variables were introduced from the beginning: age, healthcare experience, experience in current workplace, depression, anxiety, stress, exhaustion, cynicism, job inefficiency, burnout, resilience. As a method, we used the Backward Analysis method, a method that, in the end, provides the correct statistical model, after trying, one by one, all possible models, eliminating one by one a variable that is not relevant. In Table 3 we follow the value of the adjusted R2, which indicates the relevance of the model. The highest value indicates model relevance and is 0.192 in model 5. Eight models were generated.

Table 3: Model summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	0.537[a]	0.289	0.143	18.278
2	0.537[b]	0.288	0.160	18.096
3	0.534[c]	0.285	0.173	17.956
4	0.529[d]	0.280	0.183	17.848
5	0.524[e]	0.274	0.192	17.752
6	0.503[f]	0.253	0.184	17.840
7	0.492[g]	0.242	0.187	17.809
8	0.476[h]	0.227	0.185	17.825

The standardized Beta coefficients indicating the influence of the predictor variables on the dependent variable are included in Table 4.

Table 4: Standardized Beta coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
8	(Constant)	47.024	11.825		3.977	0.000
	Experience in the health field	-0.401	0.232	-0.207	-1.732	0.089
	depression	1.693	0.523	0.392	3.236	0.002
	Resilience	0.381	0.147	0.319	2.602	0.012

Following the presentation and analysis of the table with the Beta coefficients of the regression equation, the corresponding multiple regression equation is as follows:

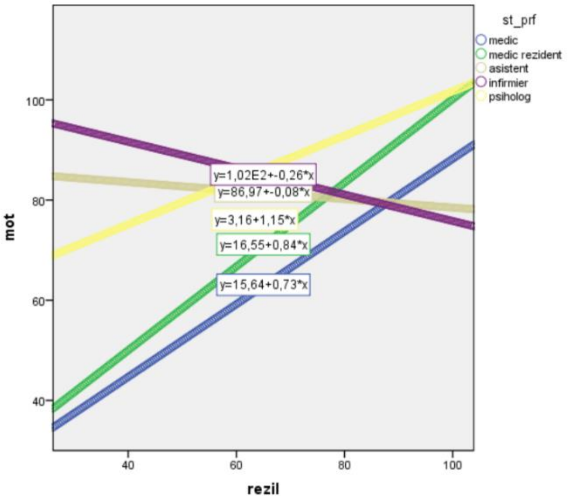
$$\text{Motivation} = 47.024 - 0.401*\text{health experience} + 1.693*\text{depression} + 0.381*\text{resilience}$$

To test Hypothesis 3, which seeks to highlight differences between the Covid ward employee group versus the non-Covid ward employee group in terms of the variables analyzed, we ran One Way Anova analysis.

Hypothesis 4: The occupational status variable has a moderating effect on the relationship between resilience and motivation. In this way, to investigate the moderating relationship, we used the PROCESS program. The dependent variable was motivation. The predictor variable was resilience. The moderator variable was occupational status [11].

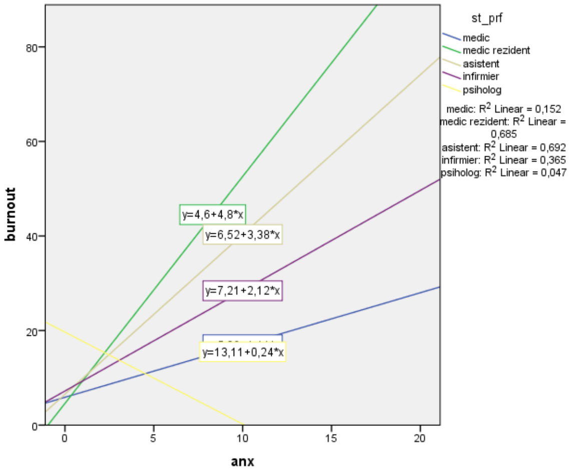
The results explain the occupational status variable as a negative moderator of the relationship between resilience and motivation at work. As shown in Figure 2, the intensity of resilience and motivation is stronger for the category of physicians, medical residents, and psychologists, as resilience is a factor strongly influencing the increase of motivation at work. This result helps us know which psychological constructs should be acted on to increase motivation at work, depending on professional status.

Figure 2



Hypothesis 5: The occupational status variable has a moderating effect on the relationship between anxiety and burnout. Thus, to investigate the moderating relationship, we used the PROCESS program. The dependent variable was burnout. The predictor variable was anxiety. The moderator variable was occupational status. As can be seen in Figure 3, the intensity of anxiety and burnout is stronger for the category of physicians, residents, hospital attendants, and nurses, with a downward slope for the category of psychologists. Thus, for the 4 categories of employees in the "psy" health care field, it is observed that an increase in the level of anxiety leads to a substantial increase in the level of burnout, with maximum intensity in the category of resident doctors, then nurses, then hospital attendants and, finally, on the attending physicians. This result helps us know which employee is more likely to develop burnout as anxiety increases [6].

Figure 3



For Hypothesis 6, we tested whether the health care experience variable has a moderating effect on the relationship between amotivation and fear of Covid. Thus, to investigate the moderating relationship, we used the PROCESS program. The dependent variable was fear of Covid, the predictor variable was amotivation, and the moderator variable was health care experience [5]. Due to some clear manifest factors (like lack of taste and smell) that could be due to some other diseases associated with Covid [12], we have had to distinguish between a pathological status versus a psychological fear.

These results explain the occupational status variable as a positive moderator of the relationship between anxiety and burnout at work.

CONCLUSIONS

A first conclusion that stands out in the present study is the regression equation for predicting the motivational level of employees in the "psy" health care field. We have shown that the regression model explains 18.5% of the motivation scale variance. The percentage is a low predictor of motivation according to the scales: depression, resilience and current work experience, however, using the Backward analysis method, which looked for the model that predicts the best, taking each variable in turn and eliminating those that were not significant. The importance that these predictor variables have for the criterion variable is demonstrated. Specifically, depression, resilience and work experience are significant predictors of motivation for several reasons [13].

Depression among staff employed in a psychiatric hospital is less obvious, as those concerned have developed adaptive coping mechanisms for dissimulation, which in crisis situations makes it difficult to highlight emotional, cognitive, decision-making and well-functioning status in the workplace as a whole. In a slightly forced terminology, we could say that many employees have concealed their depression, for fear of social stigma or the idea that for a training in “psy” it is unthinkable to give in.

Resilience is a key concept in any crisis situation. It implies adaptability, flexibility of one's own concepts and defence mechanisms, relaxation of the Superego. From this point of view, resident doctors were the most exposed, not being backed up by the necessary resilience, nor having gone through other moments of crisis in the health system. The feeling of too much professional effort in relation to the satisfaction obtained, the effort to insist by phone up to 12 hours per event to find an available place in a life-support service, the overflow even of COSU (Operational Centre for Emergency Management) resources, the delegation by the consultant of too many responsibilities for the resident doctors (some of them in their first year) or for the nurses, increased at first their anxiety, then, quite quickly, their professional burn-out. A second important finding of the research is the result that resilience and intrinsic motivation are psychological aspects that differ among medical employees between the group of those who worked with Covid positive patients and the group of those who worked with Covid negative patients. Nursing staff in the non-covid ward were under less stress, caring for an issue and pathology they were used to [6].

We also concluded that there are significant differences in the level of stress experienced by employees of a psychiatric ward, depending on their status on the ward (physician, resident doctor, nurse, clinical psychologist, hospital attendant). Psychologists have had to quickly reshape their position (while most of them were performing clinical psychology examinations, now they had to be at the patient's bedside and provide counseling and psychological support) [14].

DİSCUSSİON

Moderation analyses indicate the importance of the professional status an employee has in a medical ward in the relationships between aspects of their own and others' (employees or patients) intrapsychic lives. The fact that the intensity of motivation at work increases on the basis of resilience only for the categories: attending physicians, resident doctors and clinical psychologists can be explained by the dedication to the profession, aspirations for status, dedication to others, the need for affirmation and the need to increase their professional status. The analysis of the relationship between anxiety and burn-out, with a strong increase among all employees in the medical department, except psychologists, maybe due to exactly the aspects previously presented [7].

But, the order of increase in burn-out levels (resident doctors have the highest level of burn-out related to anxiety, then nurses, then hospital attendants, and, last, attending physicians) is also important in order to rethink responsibilities in the medical hierarchy – operationalized not "ad hoc" in crisis situations, but through well-standardized internal procedures and protocols as mentioned by Chen too [4].

Finally, the result expressing how healthcare experience positively shapes the relationship between amotivation and fear of covid brings about important insights into the need for relevant medical training at the bedside, and clinical aspects that could bring diagnostic benefits being brought to the forefront [9].

Quality of life impairments and stress coping strategies during the Covid-19 pandemic isolation and quarantine – A Web-based survey

Octavian Vasiliu[1], Daniel Vasile[1,2], Diana G. Vasiliu[1], Oana M. Ciobanu[1]

Abstract: *Isolation and quarantine during the Covid-19 pandemic affected the lifestyle and daily functioning of the population around the world, leading to social, psychological, and economic changes which further multiplied the stress related to the threat of coronavirus contagion by adding financial, relational, academic, professional and mental health vulnerabilities. To assess the impact of isolation and quarantine over the quality of life in the Romanian population, we conducted a Web-based survey focused on the evaluation of stress level, perception of lifestyle changes, communication patterns, mental health, major concerns, perception of one's future, but also on the preferred coping strategies that people have used to deal with the isolation stress. The answers were collected during one month and the results for the first 2 weeks of quarantine/isolation were compared with the results after one month of such regimen. Several recommendations based on the survey results analysis were formulated regarding possible strategies for decreasing the impact of stress factors over the general population and specific, vulnerable groups.*

Keywords: *Covid-19, pandemic, quality of life, stress coping strategies, functional impairment, depressive disorders, anxiety disorders, behavioral addictions*

QUALITY OF LIFE AND COPING STRATEGIES DURING QUARANTINE AND ISOLATION IN THE CONTEXT OF COVID-19 PANDEMIC

Quarantine is defined as a separation of people potentially exposed to contagious disease from other members of the society until the results of their analyses turn negative or until further medical interventions are needed [1]. Regarding the Covid-19 pandemic, this procedure has been considered necessary for people who traveled in the so-called ”red zones”, where high rates of coronavirus disease have been reported, and they were screened for infection initially and after two weeks of quarantine [2]. Also, the quarantine regimen involved special places for monitoring these people who were considered at risk for developing Covid-19.

Isolation is conceptualized as a separation of people who have been in contact with infected others, but who do not have any symptoms yet or have only mild symptoms, depending on national healthcare services' operational procedures [2]. This concept involves the isolation of people in their own homes for two weeks and active monitoring from their GP or Public Healthcare Services [2]. Self-isolation or lockdown is defined as a method to maintain social distancing by reducing the time spent out of the house for each asymptomatic person, and it was enforced during the Covid-19 pandemics by the law. Self-isolation is a broader

[2] Carol Davila Univesity of Medicine and Pharmacy, , Bucharest, Romania

concept but it is fundamentally a population-large method of prevention, applied in cases of contagious diseases, with a duration defined by national laws during the state of emergency. It does not involve relocation to a special quarantine-designed institution, each self-isolated person remained at his or her home for a duration specified by the law, and maintains the right to leave his/her home for a pre-defined set of specific purposes.

According to a recent review (n=24 papers), the main psychological negative effects of quarantine were post-traumatic stress symptoms, confusion, and anger, with the most important stressors being long quarantine duration, fear of contamination, frustration, boredom, lack of sufficient supplies, inadequate information, financial loss, and stigma [1]. During a SARS outbreak in Singapore, the contagious infection-related psychiatric and posttraumatic morbidity rates reached 22.9% and 25.8%, respectively [3]. According to this research, the most significant factors associated with psychiatric disorders, in general, were being seen at fever stations, younger age, increased self-blame, less substance use, while posttraumatic disorder was associated with the increased use of denial and planning, as coping mechanisms [3]. Another Web-based survey that examined the psychological impact in a quarantined Canadian population during a SARS outbreak (n=129) revealed a high prevalence of psychological distress, with symptoms of posttraumatic stress disorder and depression observed in 28.9% and 31.2% of responders [4]. A longer duration of quarantine was associated in this paper also with an increased prevalence of posttraumatic stress disorder, and acquaintance with or direct exposure to someone with a SARS diagnosis was also a risk factor for this pathology [4].

In the context of the Covid-19 pandemic complete social isolation during many consecutive weeks was considered in Italy similar to a large-scale, absolutely new social experiment [5]. Therefore, activation of healthy coping strategies could be of major importance in the prevention of psychiatric disorders onset in this population. Separation, isolation, boredom, loneliness, feelings of uncertainty are challenges for many quarantined or isolated people [6]. Healthcare workers suffered from quarantine as well, as they accused exhaustion, alienation, anxiety, irritability, insomnia, indecisiveness, decreasing work performance, etc [6, 7]. Also, healthcare personnel had more severe symptoms of posttraumatic stress disorder than the quarantined general population, experienced greater stigma, more avoidance after quarantine, were more likely to believe they had been contaminated and were more preoccupied with the risk of infecting others [7, 8].

Treatment adherence may be negatively affected by denial, anxiety, depression, feelings of despair, and also the risk of suicide or aggression should be taken into account by physicians who take care of patients diagnosed with Covid-19 [9]. Obsessive-compulsive symptoms may appear as a consequence of repeated washing and temperature checking [8]. Financial losses, societal rejection, disappointment, and discrimination are other factors that should be addressed by targeted interventions [1, 10].

Regarding the main keypoints for the psychological crisis intervention in Covid-19- diagnosed patients in China, a group of authors suggested understanding of the mental health status in different categories of population, identifying people who are at high risk of suicide and aggression, and targeted interventions for those in need [9]. Chinese researchers have established four levels of populations to design specific interventions for each one: level 1 population includes the most vulnerable people to mental health problems, e.g. hospitalized patients with severe organic diseases, frontline health care professionals, level 2 includes isolated patients with minimal symptoms and patients at fever clinics, level 3 includes people with close contacts, family members, colleagues, friends, etc, and level 4 people who are affected by the epidemic preventative measures, susceptible people and general population [9].

OBJECTIVES AND METHODOLOGY

Although stress is considered a normal response to the coronavirus pandemic, quarantine and isolation are periods of high risk for the development of stress-related disorders [11]. This risk is high especially in vulnerable populations, e.g. people with a known history of mental disorders, currently remitted or controlled by treatment, and professionals who are on the frontlines of the coronavirus pandemic (physicians, police officers, military personnel, etc), but since the lockdown was enforced by the law to the general population as a preventative measure against spreading the Covid-19, many other populations were exposed to the risk of developing stress-related disorders (e.g., elderly people, patients relying on the support of others due to physical or mental impairments, patients immobilized in their own homes, people with chronic treatments which involved regular visits to the hospital, people who were unable to work from home and who have lost their financial support, owners of small and medium enterprises that could not run their businesses during the state of emergency, etc).

The main objective of this research was to evaluate the impact of the isolation stress over the quality of life in people from Romania during the first period of the Covid-19 pandemic. The secondary objective was to find out how people have been coping with isolation-induced stress and related factors during the same period.

Data on the effect of isolation and quarantine in terms of quality of life and coping strategies were collected through an online survey that could be completed by the respondents between the 21st of March and 20th of April 2020. During one month, 941 respondents answered the online survey, and their answers were analyzed after the first two weeks (n=103) and at the end (n=941) of the before-mentioned period. A comparative analysis of the responses from the two stages was also performed.

The survey was entitled "The psychological impact of the Covid-19 pandemic in the population subjected to self-isolation/quarantine" and consisted of 34 questions (Q1-Q34), with a completion time of 10-15 minutes. The answers of the people who completed 100% of the survey questions were analyzed (n=941).

QUALITY OF LIFE IMPAIRMENTS AND COPING STRATEGIES TO STRESS DURING THE COVID-19 PANDEMIC

Respondents were adults (81.5%), elderly (17.5%) and adolescents (1%), coming from urban (86%) or rural (14%) environment, both citizens from Romania (97.3%) and Romanian citizens residing in other countries (Great Britain, Germany, Austria, Canada, the Republic of Moldova, Tunisia, Belgium, the Czech Republic, Spain, Cyprus, Portugal, Italy and the USA, 2.7%). The respondents were female (81%) or male (19%), and they were married 54.7%, unmarried 23.7%, widowed 8.6%, or divorced 13%.

People who completed the questionnaire were living mostly in self-isolation for prophylactic purposes (68%), in quarantine (6.5%) or isolation (symptomatic) (3%), for one week (11, 5%), two weeks (8.5%) or more than 14 days (80%) (Figures 1 and 2).

The respondents were professionals from the medical staff (10.5%), police officers and auxiliary personnel (1.2%), workers in trade business with direct contact with potentially-infected people (5.3%), or were professionals involved in other high-risk categories of contracting Covid-19 (12.3%). Answers provided by respondents who did not fall in any of the previously mentioned professional categories represented 70.7%.

The educational background of the respondents was university (43.4%), postgraduate (24.6%), or high school (19.2%).

Survey respondents lived in the same home with children up to 7 years old (9%), children aged 8-14 (6.7%), adolescents (11%), elderly (over 65 years old) (12.7%), people with disabilities or other severe illnesses (2%), people undergoing treatment for various organic diseases (5.6%), people diagnosed with mental disorders and currently on specialized treatment (1.1%), or people who took care of other vulnerable individuals (3%). Among the respondents, 3% had mental disorders and were currently receiving treatment, while 13% had somatic disorders.

Figure 1: In which situation are you now? (Q2)

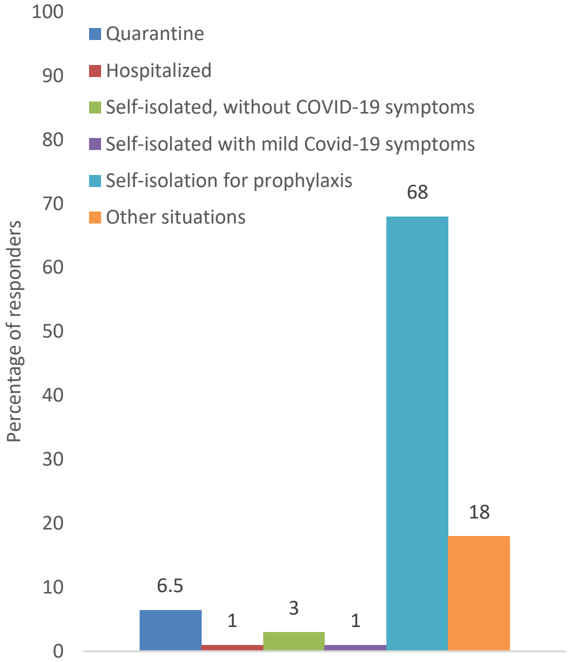

Figure 2: How long have you been in isolation or quarantine? (Q3)

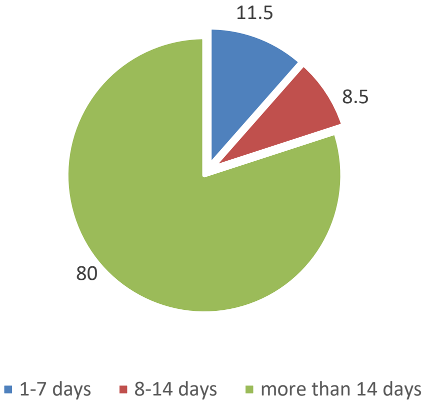
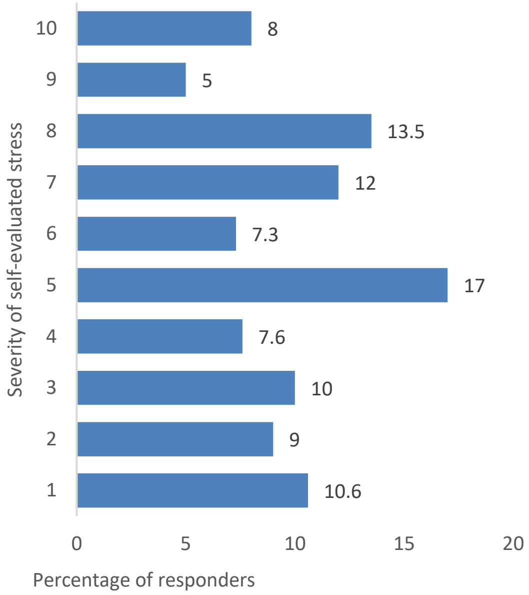


QUALITY OF LIFE IMPAIRMENTS DURING COVID-19 PANDEMIC- ASSOCIATED QUARANTINE AND ISOLATION

The level of stress induced by isolation or quarantine was felt differently by respondents, ranging from absent (10.6%) to extreme (7%) (Figure 3). Most of the respondents considered the level of stress associated with the quarantine or self-isolation regimen to be moderate (35.6%).

Communication is an important aspect of the quality of life in isolated populations, and changes in the communication patterns may have significant repercussions over people's social and psychological health. Our respondents continued to communicate with their relatives and friends by telephone calls (44.5%), through social networks using their smartphones (43.5%) or other electronic devices (laptop/ tablet/desktop) (10.1%) (Figure 4).

Figure 3: How do you evaluate the severity of the quarantine/ isolation-induced stress, from 1(absent) to 10 (extreme)? (Q11)



Inadequate information may negatively impact both mental health and quality of life, by raising the level of stress and fostering cognitive distortions. Most of the respondents collected data about the Covid-19 pandemic from the Internet (official sites) (57.5%), television (31.3%), Internet blogs and unofficial sites (5.3%), online or printed press (3.8%), and other sources (1.1%) (Figure 5). The majority of respondents stated they spent a maximum of one hour daily to find out news about the Covid-19 pandemic (71%), while 25% spent between one and 5 hours each day for the same purpose.

Regarding the most important concerns during the lockdown/quarantine that may influence the quality of life, our respondents mentioned primarily the concern about the health of those close to them (43.7%), then the concern related to their health (15.8%), followed by worries triggered by the family's financial security (12%), her or his financial future (7%), and his or her professional perspectives (4%). Other concerns reported by respondents were: the difficulties in running their own business, the current socio-political situation, the obligation to be vaccinated if a vaccine is to be discovered, the inability to continue daily routines they had before the pandemic, the restrictions applied to the freedom of movement, the restrictions applied to the access to religious services within the church, limitations to the professional/school activities, the collective mental health, the global economic crisis, the loneliness, the possible shortcomings in food production. About 13% of respondents did not mention any significant current concerns related to the Covid-19 pandemic that may relate to their quality of life.

Figure 4: How did you continue to communicate with your family, friends, neighbors during the isolation/quarantine? (Q13)

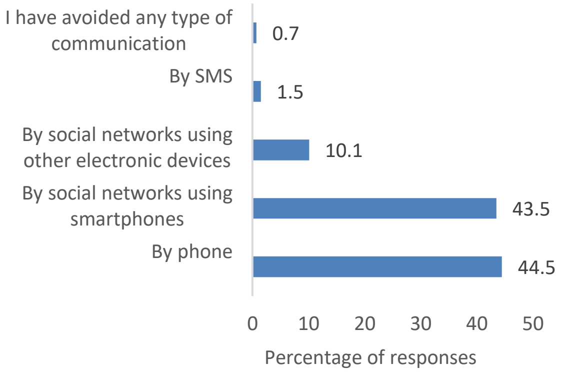


Figure 5: Where did you get your information about the CoViD-19 pandemic? (Q14)

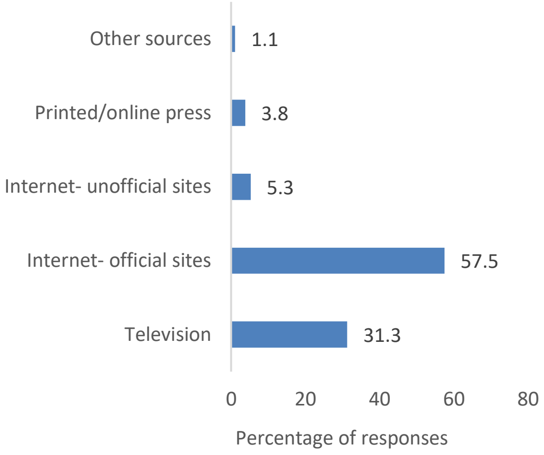
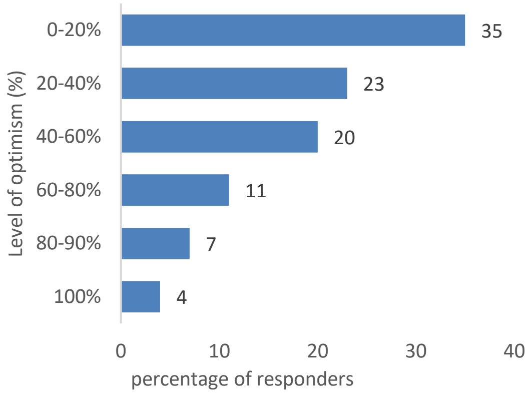


Financial aspects of quarantine and isolation have a significant potential to trigger changes in one's quality of life. During the period of self-isolation, 38.2% of people stated that they could work from home, without financial differences (20.8%), or with financial losses (17.4%), while

11% were in technical unemployment. It should be mentioned that 15.1% of the people stated they cannot work from home or receive financial support for this period, and a significant percentage of the respondents cannot work from home at all, because they have professions that cannot be done from distance.

Regarding the degree of optimism, respondents admitted a low (43%) or very low (35%) level, with only 20% recognizing a moderate level and 22% a high level of confidence in the possibility of solving the epidemiological crisis in the short-term (2-4 weeks) (Figure 6).

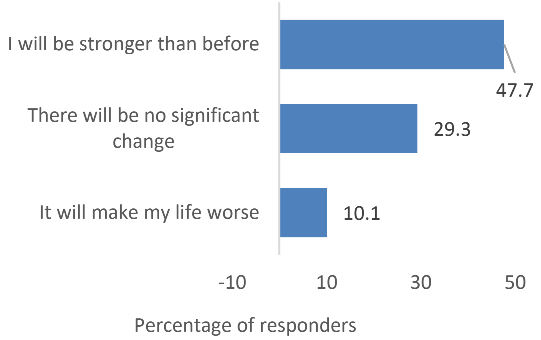
Figure 6: How do you rate your level of optimism regarding the possibility of solving the problem of the pandemic in a short time? (Q23)



The way people look at their future is important for evaluating the quality of life in any population. Asked how they estimate their life will change as a consequence of the Covid-19-related (self)isolation/quarantine, the survey respondents said they expect to emerge stronger from this experience (47.7%), or that they will not suffer any medium or long-term negative impact of isolation (29.3%) (Figure 7). Only 10.1% of respondents consider that this experience will have a significant negative and permanent impact on their lives.

Regarding the appearance of psychopathological symptoms with functional impact during isolation, respondents mentioned insomnia (11.5%), nervousness/irritability (9%), unmotivated physical/mental fatigue (6.4%), panic (6%), catastrophic expectations related to pandemic (6%), increased appetite (4.5%), depressed mood (4%), decreased appetite (2%), crying spells (2.5%), ideas of uselessness or lack of self-worth (2.5%), concentration problems (2.2%), anhedonia (2.2%), feelings that life is meaningless (1.7%), drowsiness (1.7%), numbness in the hands or feet (1.6%), palpitations (1.6%), de-realization (1.3%), physical pain without an organic cause (1%), and many respondents admitted the presence of at least two of the listed symptoms. About 30% of respondents stated they did not experience any symptoms from the list presented.

Figure 7: What do you think that will change in your life as a result of isolation/quarantine? (Q29)



The communication with health services is another variable that may be correlated with the quality of life, especially during a world-scale epidemiological crisis. It should be noted that only 3.8% of the respondents sought the help of a mental health specialist during lockdown and quarantine. Of the people who went to the psychiatrist, 1% were already in treatment and adjustments of the current therapy were recommended, 1.2% were prescribed treatment for the first time, 0.5% did not receive any psychotropic treatment, being scheduled for a reassessment after the period of self-isolation/quarantine, 2.7% received a recommendation for online counseling/psychotherapy, and 40.1% did not receive a recommendation for any drug treatment or psychotherapy.

Of the patients who had medication recommended for any condition before self-isolation/quarantine, most of them stated that they were able to obtain the prescribed medications, but some people reported difficulties in procuring their usual medications (for hypothyroidism and diabetes, for example). Many respondents mentioned that they have appreciated the newly-launched system of electronic prescriptions sent by the physicians, without having them to travel to the doctors' office.

In terms of harmful behaviors with onset during the Covid-19-related self-isolation/quarantine, 23% of respondents ate more than before, 16% increased cigarette daily consumption, 9.6% resorted to excessive online shopping, which they later regretted, 5% took by themselves medication for sleep, and 4% increased alcohol use compared to their reference level. Other significant changes were abusive use of the Internet and changing in the sleep-wake rhythm, by advancing bedtime and waking up later than usual, and increased consumption of sweets. Changes in the physician-prescribed diet have also been reported, because people with dietary restrictions found harder on the market certain foods during this period. However, some respondents mentioned the appearance of certain favorable changes, stating that "I appreciate life more now", "I appreciate much more everything beautiful around me", "I treasure my health more", "I appreciate the freedom more”, “I have managed to quit smoking”, “I realized that I can adapt to more difficult situations without repercussions on my psychological status”.

COPING STRATEGIES DURING COVID-19- RELATED QUARANTINE AND ISOLATION

Interaction with other family members in self-isolation was the preferred method of coping with the situation (17%), followed in descending order by use of the Internet - social networks (13.4%), television – entertainment programs (12%), reading (11%), gardening (9%), Internet – entertainment (6%), Internet – online games (3.8%), television – news editions (3.6%), smoking (3.5%), sportive activities at home (3%), religious activities performed at home (3%), crosswords/sudoku/puzzles (2.6%), DIY (2.3%), Internet – educational programs (2%), board games with other self-isolated family members (1.6 %), Internet – shopping other than those of vital necessity (1%), television – cultural programs (1%) and alcohol consumption (0.75%).

When asked what they would advise other people placed in isolation to do while they are inside their homes, respondents said the best coping methods would be: structuring the daily program, in which to include activities as diverse as possible (e.g., "to arrange for the next day at least two activities that he/she likes"); to exploit the available time they have for doing things they have not been able to do so far because of the procrastination; to be patient, to keep calm and to follow the rules, to think about the fact that it is only a period that will pass; to do gymnastics or any kind of sport, in the house or outside; to adopt a pet; to get involved in religious activities that can be carried out at home; to avoid continuous contact with news programs (e.g., "to filter the information they receive very well", "to be informed about the current situation from the TV or other sources only if necessary"; "to watch the news only once daily”); to listen to cultural programs on the radio; to continue their professional activity at home, if possible; to discover new hobbies ("to discover something they will enjoy", "to do something creative"); gardening (e.g., "those who can move to a house with a garden should do it", "even if you are living in a flat you can take care of flowers, because flowerpots can be placed on the balcony"); to take advantage of free time and spend it with loved ones, to communicate with the family by phone/social networks (e.g., “those who have children should enjoy these moments, going to work usually robs us a lot of time that we should spent with our children”, “to communicate daily with the children and with the family by phone/Internet”); to reflect on the self (e.g., "to explore the self as much as possible using all the means at their disposal"), meditation, yoga; to clean the house in an organized way; to watch new movies with his/her family, but also to watch old movies, which he/she likes; crosswords, sudoku; Internet- games, social networks, entertainment (e.g., shows broadcasted online), personal development trainings, parenting, etc.; sewing, tapestry, embroidery, crocheting, knitting, tailoring; DIY; cooking (e.g., "to try to prepare new things in the kitchen, to explore..."); drawing, painting; music (e.g., "to listen to music daily, especially relaxation music"); reading (e.g., "to read some of the books we have long wanted to read"); development of skills that could be useful after the end of the pandemic- language courses, acquisition of professional qualifications or overspecializations, computer skills trainings (e.g., "to look for information related to a specialization in a new field"); to study what they wanted to study but failed due to lack of time; board games with other family members in the house; to keep a diary of this period; to avoid food excesses and to focus on a healthy diet; to build plans for the future (e.g., “to plan their activities in the post-isolation period, to take into account what they want to do, who they want to see”).

To the question "What do you not recommend to other self-isolated people to do?" the most common responses were: to avoid prolonged lying in bed during the day; to avoid binge-watching TV (e.g., "do not watch news programs for more than an hour daily") and to avoid data collected from unauthorized sources; avoid alcohol use and excessive smoking; do not do excessive shopping; do not isolate themselves emotionally; do not fall prey to monotony; do not consume excessively sweets and rich-calories foods in general; do not take medication without a doctor's recommendation; to avoid leaving the house if it is not necessary; to avoid excessive discussions on social networks about coronavirus; to avoid self-victimization and panic; do not abuse the Internet; to avoid online gambling; to avoid alcoholic drinks and to not increase the number of daily cigarettes.

Communication with people living in the same home was not significantly affected, according to the majority of respondents placed in isolation/quarantine. They stated that they enjoyed the time spent together, this time is an opportunity for mutual discovery or closeness. Such responses were, for example, “This isolation strengthened the connection between us, divergences faded, we mobilized to face a general threat together”, “We found, after a long time, the pleasure of time spent together; we have different stages of life but we have re-discovered common interests/opinions”, “I think this period has approached us”, “We had enough time to discuss everything we had not discussed so far”,“ Self-isolation facilitated communication between me and other family members, we had more time to spend together, a time we would not have allocated to ourselves if it were not for these extreme circumstances", "If it were not for the crisis, everyone would have had other things to do and we would have inadvertently avoided this approach".

There were however signals about monotony or increased nervousness - "Stress level is quite high, not everyone understands self-isolation measures", "This period increased our stress and made us feel trapped", "We became more irritable towards each other, because we spent too much time together”, "Because of the stress and anxiety there were more and more discussions and sometimes quarrels". There have also been situations when ignoring others has been reported as a method of coping with interpersonal stress.

The following reactions were reported during the communication with people (family, friends) outside the respondents' home: frustration due to lack of intimacy (“Emotionally, lack of contact with loved ones generates frustration”, “It is difficult not to have meetings, we can't enjoy the outdoors together", "I'm sorry I can't physically express my love for them", "I’m afraid we will become estranged"), worries about changing one's self and one’s relationships ("We became more lonely, more suspicious, more indifferent to each other”), concerns about the impact of one’s professional status over the family members (“I have to go to the hospital every day, being a doctor, and the family is worried about my health”), concerns about lower income that can affect family members, lack of food supplies on the markets, lack of enough anti-Covid-19 protective materials), reassessment of previous social experiences (“I miss my work colleagues, even those I did not value enough”). Some people tried to focus on the positive aspects ("We have more time to discuss, to talk about anything... For the first time I talked to my child for an hour without arguing", "It's hard not to see each other, but I know that's how we protect ourselves and others”,“ We communicate better”, “I think now I have time to talk to more people than before”).

Religion is seen as an important coping method by 47% of those in isolation or quarantine, even if participation in religious rituals was not allowed within the churches during the emergency state.

For people living with children in self-isolation/quarantine, the most commonly used methods of organizing children's time were encouraging online communication with classmates (7%), continuing school training (6.2%), board games (3.9%), encouraging participation in physical exercises (3.1%), unrestricted use of the Internet (“let them stay on the Internet as long as they want”) (2.8%), watching TV programs (“we do not limit access to watching TV anymore to a certain amount of time”) (0.8%).

Regarding the communication with children about the Covid-19 pandemic data, 32% of parents responded that they tell them what is happening and maintain constant communication with them about the pandemic, while 16% prefer to distract their attention from what happens through the use of games or other means. Almost 7% of the parents prefer to tell them that nothing bad is happening and that it is just a form of holiday, and only 2% said they forbid their children to come into contact with information sources about pandemic or do not answer children’s questions about the pandemic openly.

DYNAMIC INTERPRETATION OF THE QUALITY OF LIFE AND COPING STRATEGIES DURING THE QUARANTINE OR ISOLATION

Between March 21 and April 7, 2020, 103 respondents completed the online survey, and between April 8 and 20, 2020, the number of respondents reached 838. The interpretation of the answers must take into account the significant change in the demographic distribution of the participants, respectively an increase of the percentage of elderly people from 2% to 17.5%, with the corresponding decrease in the number of adults aged between 18 and 64 (95% vs. 81.5%), while the number of adolescents remained relatively constant (1% vs. 3%). Also, the marital status of the respondents was different, with an increase of the proportion of married (40% vs. 54.7%) and divorced people (3% vs. 13%), in parallel with a decrease in the number of unmarried people (55% vs. 23.7%). No major differences were observed in the geographical distribution of respondents (urban vs. rural, people located in Romania vs. Romanian citizens located in other countries). From the point of view of the educational background, a higher number of people with high school answered the questionnaire in the second stage of the survey, so that their proportion increased to 19.2% vs. to 9% in the first stage. Respondents who were not in those categories involving a professional risk of contracting Covid-19 increased from 56.5% to 70.7%, a difference that may be correlated with the change in the age of the respondents.

The people who completed the questionnaire were mostly self-isolating for prophylactic purposes both in the first half of the month and at the end of the one month, but the duration of the isolation regimen increased, as expected - the proportion of those who stayed in the house for more than 14 days was at the end 80% vs.11.7% at the half of the evaluation duration. The proportion of those who cared for children, adolescents, or the elderly was not significantly different in the two situations, as was the proportion of those who had mental or organic disorders in treatment.

The level of stress induced by isolation/quarantine did not change much over time, the proportion of those who consider this parameter to be moderate was 33% at two weeks and 35.6% after 4 weeks, those who considered it not significant were more numerous (6% vs. 10.6%), and the percentage of those who considered it unbearable also increased slightly (5% vs. 7%).

Interaction with other family members in self-isolation was the preferred method of dealing with the situation after two weeks and remained so at week 4 (23.5% and 17%, respectively).

Several coping strategies have increased their frequency of use – for example, use of the social networks (12% vs. 13.4%), watching entertainment programs, music, movies, television documentaries (10% vs. 13%), interest in gardening (4% vs. 9%), DIY (1% vs. 2.3%), smoking (3% vs. 3.5%), home sports/gymnastics (less than 1% vs. 3%), crosswords/sudoku (1% vs. 2.6%) and religious activities at home (less than 1% vs. 3%).

From the category of methods that have remained at the same level throughout the 4 weeks of the survey was the interest in reading (10% vs. 11%), sportive activities at home (8%), TV news (3% vs. 3.6%), Internet- educational programs (2%) and Internet- online shopping (1%). There was a slight decrease in the interest in Internet-entertainment and online games (13.5% vs. 9.8%), inboard games with other family members (3% vs. 1.6%), but also in the interest for alcoholic drinks (2% vs. 0.75%).

Respondents continued to communicate with those close to them by phone, through social networks on mobile phones or other electronic devices (laptop/tablet/desktop) in similar proportions in the two stages. Most respondents informed themselves about the Covid-19 pandemic from the Internet (official sites) (69.6% vs. 57.5%), but also unofficial sites or blogs (less than 1% vs. 5.3%). More respondents preferred to inform themselves from television at week 4 (22.5% vs. 31.3%), while the press remained at a constant level of interest (5% vs. 3.8%). Most of the respondents stated they have spent a maximum of one hour daily to find out data about the Covid-19 pandemic in a slightly increasing percentage (64.7% vs. 71%), while the number of those who spend between one and 5 hours each day for the same purpose decreased slightly (30.6% vs. 25%).

Asked what they would advise other people situated in isolation to do while they are inside their homes, the respondents offered the same categories of answers, namely those focused on the accuracy of information (using only official sources), spending more time with hobby activities, structuring of the daily time (including a list with various daily activities), caring for other family members with whom they live, communicating with friends/relatives outside the home by electronic devices, building plans for the future, developing new skills, adhering to the principles of healthy eating, practicing activities they have postponed due to lack of time, rediscovering themselves through specific activities (online personal development workshops, meditation, yoga). New recommendations have emerged regarding religious activities practiced at home, in the context of the Easter holidays.

To the question "What do you not recommend to other people in self-isolation to do?" the most common responses were similar in the two-time intervals assessed, namely avoiding long-term exposure to news programs, avoiding excessive eating, avoiding lack of activities during the day, avoiding leaving the house if it was not necessary, avoiding excessive discussions on social networks about coronavirus, avoid self-victimization, panic, and monotony, avoid alcohol use and excessive smoking. There were also recommendations to avoid prolonged bedtime during the day, excessive shopping, abuse of sweets, and high saturated fat foods, online gambling, and abuse of the Internet.

Communication with people situated in the same house was not significantly affected, according to the majority of respondents in self-isolation after two and 4 weeks, with a predominance of people who showed that they enjoyed the time spent together, this interval being considered an opportunity for mutual discovery or closeness.

During the communication with other people (family, friends) outside the respondents' homes, the following reactions were reported: frustration due to lack of privacy, concerns about the impact of professional status on the family’s general wellbeing, concerns about the lack of finance that may affect family members, reframing of the previous social experiences, but also equilibrium or even focusing on the positive aspects of the situation. Besides, concerns were raised about changing one's person and one’s relationships, which could be long-lasting, according to the respondents.

Regarding the most important concerns of this period, respondents mentioned especially the anxiety related to the potential health issues of the loved ones (67% vs. 43.1%, decreasing trend), then those related to their health (11.6% vs. 15.8%, increasing trend), followed by those fears triggered by financial uncertainty, professional or school prospects and the global political context.

During the period of self-isolation, 54% of people stated that they can work from home without financial differences (35% vs. 38.2%, slight increase), or with financial losses (14.5% vs. 17.4%, slight increase), while technical unemployment affected an increasing proportion of people (4% vs. 11%). It should be noted that 12% (after two weeks) and 15.1% (after 4 weeks) stated that they could not work from home or receive financial support for this period, and a significant percentage of respondents were not able to work from home at all due to the specifics of their jobs.

Regarding the level of optimism, respondents admitted a reduced level after 4 weeks comparative to the 2-week level (26% vs. 43%), only 20% admitted a moderate level, and 9% vs. 22% (significant increase) a high level of confidence in the short-term resolution (2-4 weeks) of the epidemiological crisis.

Religion was seen as an important resource for a growing proportion of people (33% vs. 47%) in self-isolation/ quarantine after 4 weeks comparative to the 2-week level.

For people living with children in self-isolation/quarantine, the most commonly used methods of organizing children's time were online communication with colleagues/teachers, board games, continuing school training program, then using the Internet, physical exercises, and watching TV. Regarding communication with children about Covid-19 pandemic data, a similar percentage of parents responded that they tell them what is happening and maintain constant communication with them about the pandemic (35% vs. 32%), while 17% vs. 16% prefer to distract them from what is happening outside by using games or other means.

Asked how they estimate they will be affected by self-isolation/quarantine, respondents said they expect to emerge stronger from this experience (55% vs. 47.7%, decreasing trend), or that they will not suffer any medium- or long-term negative impact of isolation (31% vs. 29.3%, relatively similar percentage).

Regarding the onset of psychopathological symptoms with functional impact during isolation, respondents mentioned insomnia (10% and 11%, respectively), followed by nervousness/irritability (10% vs. 9%) and anxiety/panic (5% vs. 6%, increasing trend), catastrophic expectations related to the pandemic (6%, increasing trend), unmotivated physical or mental fatigue (7% vs. 6.4%). Other reported symptoms were depressive mood (8% vs. 4%, decreasing trend), increased appetite (7% vs. 4.5%, decreasing trend), concentration problems (7% vs. 2.2%, decreasing trend), and several people have reported clusters of symptoms.

However, only 4.8% of the respondents sought the help of a mental health specialist during isolation/quarantine after two weeks and 3.8% after 4 weeks. Of the patients who had medication recommended for any condition before isolation/quarantine, most of them said they were able to purchase their prescribed medications.

During isolation/quarantine, harmful behaviors such as excessive online shopping decreased in time (13% vs. 9.6%), alcohol consumption compared to the previous level also decreased (7% vs. 4%), excessive smoking was increasingly reported (13.5% vs. 16%), and self-administered sedatives significantly increased (1% vs. 5%). Other important changes were the more intense use of the Internet and change in the sleep-wake rhythm by advancing the bedtime and waking up later than usual, and also an increase in the sweets consumption. After 4 weeks, changes in the structure of the diet were reported, people who had a diet recommended by the doctor stating that they can no longer buy those specific foods. After 4 weeks, some favorable changes were mentioned, such as raising awareness of the importance of life, health, and loved ones.

CONCLUSIONS AND RECOMMENDATIONS

The dynamic self-assessment of the stress level induced by isolation or quarantine in the context of the Covid-19 pandemic did not show significant changes between the analysis performed after two weeks and the one performed after 4 weeks. This stress level was very different from one respondent to another, being quite evenly distributed from absent to extreme, most often being chosen the average values. It should be noted that almost 50% of the respondents were caregivers for minors, elderly people, patients with organic or mental illnesses so that they were confronted with multiple stressors.

The most commonly reported coping methods used to deal with the stress of self-isolation were (1) direct communication with other family members with whom the respondents live, or by phone/Internet with loved ones who live outside their current place of isolation; (2) online entertainment (network games, movies, documentaries) or TV (movies, entertainment programs, sports); (3) reading,

(4) sports activities; (5) other – gardening, board games with other family members in isolation, TV news programs and educational programs (either TV or online); (6) keeping a diary, or planning daily activities for efficient time management; (7) personal development (online courses, meditation, yoga); (8) development of any professional skills that may offer an advantage on the labor market in the post-pandemic period (online language courses, computer programming workshops, overspecializations in one's field of activity, etc.).

It should be noted that the frequency of excessive smoking has increased after more than two weeks of isolation or quarantine, and this can be a dysfunctional coping method to deal with the isolation stress. Adequate measures of psychoeducation could be useful at the populational level for the prevention of excessive smoking, as well as dissemination of recommendations for adequate time management so that smoking can be replaced by relaxation methods free of harmful effects. Other dysfunctional coping methods were reported during self-isolation, namely, excessive online shopping, which was later regretted by the people concerned; compulsive eating, especially of sweets or other high-calorie foods; self-medication for sleep disorders; Internet abuse. In this regard, it should be noted that lockdown is a period during which behavioral addictions can develop unhindered if they are not actively fighting against - for example, the diet should be balanced to avoid the abusive use of sweets, between meals high-calorie foods are prohibited, prolonged sitting in front of the computer or TV should be considered harmful by people in isolation, and it is recommended to introduce active relaxation breaks between sessions of Internet or TV use; abusive online shopping or online gambling must be perceived as dangers and campaigned against; sleep medication should be taken only on prescriptions from a physician, strictly for the recommended duration.

The use of social networks and phone callings were used by respondents in relatively equal proportions to keep in touch with those close to them. The Internet was preferred as a source of information over television, but this is most likely the result of how respondents were selected (online platforms); the time spent daily informing about the Covid-19 pandemic has been reduced (over 70% estimated this time to be one hour), which indicates a realistic approach and avoidance of intoxication with data about the pandemic.

The main recommendations offered by the respondents for other people in isolation or quarantine were: (1) sports and relaxation activities (Pilates, yoga, gymnastics); (2) hobby activities (cooking, gardening, tapestry, drawing, dancing); (3) communication with loved ones; (4) caring for loved ones; (5) information only from official sources; (6) reframing of the current situation („you may consider that it is a holiday, a period of self-evaluation, of rediscovering your partner, of making plans for the future"); (7) developing new professional skills that may be useful in the future; (8) religious activities performed at home.

Contraindications that respondents considered important during self-isolation: (1) prolonged exposure to news programs; (2) self-blame and panic (it must be taken into account that the situation is limited in time anyway); (3) avoid excessive eating, smoking, and alcohol abuse; (4) avoid monotony by diversifying the daily program; (5) avoid unnecessarily leaving of one's own house; (6) avoiding lying in bed during the entire day; (7) avoid excessive consumption of sweets, online gambling and excessive use of the Internet.

Most of the people stated that there were no changes in communication with their loved ones who lived in the same house. However, from the category of those who felt such changes, most of them showed that they managed to enjoy the time spent together, using this period constructively and finding common interests and activities with their partner/children/other relatives in the house. The appearance of nervousness installed on the background of isolation-induced monotony was also reported, which leads to the need of implementing coping strategies based on the detection of common interests, on the practice of relaxation exercises, etc; ignoring one's partner or spouse was also signaled as a dysfunctional coping strategy, and in this case, we consider as optimal strategies the resignification of the situation, finding hobbies that several people from the same house may share, establish common plans for the future.

Communication with those outside the home was marked by (1) the feeling of lack of privacy which is commonly associated with physical, direct communication; (2) concerns about how the economic situation (technical unemployment, working from home with declining income, or even lack financial support) and social situation (separation from the group of colleagues, neighbors, friends) will affect oneself and his/her family; (3) emotional balance (acceptance of the current situation and associated changes of the communication paradigm); (4) capitalizing on current resources (using the time constructively, communication targeting the reconnection with old friends and relatives with whom they have not spoken for a long time, etc).

The respondents' main concerns were (1) worries related to the health of people close to them and their health; (2) financial security; (3) professional or academic future. Therefore, the officials should communicate more with the population about these issues and offer them adequate information about the pandemic-imposed crisis changes in the economy and academic activities.

The level of optimism regarding the resolution of the situation within a maximum of one month was reduced to 43% of the respondents, which shows a high level of awareness of the importance of the epidemiological situation.

Parents who live with their children at home have found as a means of organizing the children's time using board games within the home, the continuation of the school training program from home, then using the Internet for entertainment, online communication with colleagues and teachers, physical exercises and watching TV. The communication with the children regarding the Covid-19 pandemic data was good, in the sense that it was based on respecting the facts, with the concepts being formulated inappropriate terms.

The respondents did not expect self-isolation to change their long-term lifestyle, or even had favorable expectations, respectively to come out stronger from this experience, which shows a high level of confidence in their resources to cope and an effort to integrate this experience into the continuum of their life.

Psychopathological manifestations have been reported during self-isolation, in particular insomnia, nervousness/ irritability, anxiety/panic, unmotivated fatigue, depressed mood, appetite changes, concentration problems, and many people have shown symptomatic clusters, not just isolated symptoms. These elements had a recent onset and they can be largely attributed to the stress-induced by isolation or quarantine, given that only 3% of the survey respondents admitted to pre-existing mental disorders.

There was reported a reduced addressability to psychological or psychiatric services, while the use of one's methods of coping with symptoms increased in time (self-medication for sleep, coffee for drowsiness, alcohol for anxiety). Therefore, less than 4% of the respondents used the help of a mental health specialist during their isolation/ quarantine. These phenomena show not only that there is a risk of developing mental disorders in this period, especially anxiety and depressive disorders, which are to be expected in this period of isolation/quarantine, but also the risk that these disorders worsen rapidly in the absence of mental health-focused interventions. In this context, the possibility of accessing online medical platforms and psychological helplines dedicated to people going through difficult times should be disseminated into the population as an important means to prevent the worsening of stress-related disorders. Pharmacological treatment and psychotherapy should be used for anxiety, stress-related, and depressive-spectrum disorders, whenever needed [12]. Vulnerable populations to the isolation or quarantine-associated stress, represented by elderly patients, people with a psychiatric history or physical impairments should benefit from special attention from the mental health specialists, and special programs designed for the awareness of anxiety and depressive disorders should reach them through the media, general practitioners, or any official vector of information possible [13]. Depression is an important factor for lowering the quality of life and harms life expectancy so that it should be treated actively whenever detected [14, 15].

Disclaimer

No conflict of interest to declare. No financial support was received from any governmental institution, economic or non-governmental organization. No personal information was collected through the survey, the anonymity was preserved for all the respondents.

Redo procedure following Zenker`s diverticulum treatment – a clinical study

Diana Ciuc[1], Dinca Gabi-Valeriu[1], Peta Dumitru[1], Marcel Tanțău[2], Marica Cristian[3], Achim Florin[3], Eugenia Panaitescu[3], Rodica Bîrlă[3], Silviu Constantinoiu[3]

Abstract: *Introduction: The prognosis of patients with Zenker`s diverticulum is dependent mainly on the type of procedure performed, either surgical or rigid/flexible endoscopy.*

Purpose - evaluation of the redo procedure by reviewing correlations in patients with iterative procedures.

Material and Methods: We included in the study 36 patients with cervicomediastinal Zenker diverticula treated from 2010 to 2017 at two university hospitals: Clinic of General and Esophageal Surgery. Mary Clinical Hospital Bucharest and Department of Diagnostic and Interventional Digestive Endoscopy of the Regional Institute of Hepatology and Gastroenterology Prof. Dr. Octavian Fodor, Cluj-Napoca. For the patients included in the study we studied correlations of patients with symptoms persistence and to those with reintervention with epidemiological, clinical and the treatment criteria.

Results: Postprocedural symptoms we observed in 5 patients of the 29 treated endoscopically and 6 of the seven treated surgically. Statistical correlations were noted in patients with persistent symptoms after surgical treatment ($p < 0.01$) with patients with diverticulectomy (54.5%) ($p < 0.01$), grade III diverticula (36.4%) ($p < 0.01$) statistical association was noticed in patients who have required reoperation and those with persistent symptoms (63.6%) ($p < 0.01$) and with remaining dysphagia (100%) ($p < 0.01$) and those with grade 2 dysphagia persistence (71.4%) ($p < 0.01$), grade 3 diverticula (42.9%) ($p < 0.03$) and the high number of comorbidities. ($p < 0.04$)

Conclusion: Undoubtedly, endoscopic treatment is being used more and more even for those cases that require further treatment. Reoperation has been necessary for patients with persistent dysphagia with voluminous diverticula and a high number of comorbidities.

Keywords: *diverticulum Zenker, endoscopic diverticulostomy, diverticulectomy, iterative procedure*

INTRODUCTION

Zenker`s diverticulum is a cause of morbidity in elderly patients. According to van Overbeek's theory, the predominant role in diverticulum formation has an anatomical predisposition represented by Killian dehiscence weakness. [1] The externally surgical approach has long been the conventional treatment with satisfactory clinical success rates ranging from 80-100%. [2]

The prognosis for these patients depends on the surgical procedure performed. Some authors stated that diverticulectomy patients have a long-term symptom recurrence rate of 2% to 33%. [3] Studies have been published since 1981, which noted that surgical resection or suspension of the pouch performed without a concomitant

myotomy fails to improve dysphagia and fail to prevent complications or recurrence of the diverticulum, a fundamental consideration of the endoscopic techniques developed later. [4]

Some authors found that patients with endoscopic stapler technique, have a long-term symptom recurrence rate ranging from 0 to 47%. Most authors consider that the reasons for symptomatology after the endosurgical approach is the incompatibility of the dimensions of the septum with the length of the stapler (3 cm). A small diverticulum limits access to the tip of the stapler and it may not be possible to perform a proper myotomy. [5]

Data from the literature indicate a recurrence rate for laser endoscopic diverticulostomy of about 5-25%. [6, 7]

Flexible endoscopic therapy is a relatively new approach compared to rigid endoscopic and surgical techniques. Data from the literature on flexible endoscopic therapy show that symptomatic improvement was observed at 85%, with a symptom recurrence rate of 18-20%. [8-11]

The higher recurrence rate after flexible endoscopic treatment could be caused by incomplete septal dissection. Some authors have shown that the success of the treatment correlates with the length of the septotomy. The risk of perforation by over dividing muscular fibers and difficult identification of the last fibers of the cricopharyngeal muscle could make the endoscopist to leave a residual part of the septum to avoid perforation into the mediastinum. [12]

MATERIAL AND METHODS

We included in the study group 36 patients with Zenker diverticula treated during 2010/2017 in two university hospitals: Clinic of General and Esophageal Surgery Sfanta Maria Bucuresti and Department of Diagnostic and Interventional Digestive Endoscopy of the Regional Institute of Hepatology and Gastroenterology Prof. Dr. Octavian Fodor, Cluj-Napoca.

Inclusion criteria: patients with Zenker diverticulum admitted and treated endoscopically or by open surgery in the hospital during 2010/2017, over 18 years of age, investigated with barium swallow and upper GI endoscopy, patients with a follow-up period of at least 12 months post-procedure.

Exclusion criteria: immunocompromised patients, patients with associated malignant disease, patients lost from post-procedure follow-up.

All patients in the group were investigated by clinical examination, imaging with a barium swallow, upper endoscopy and functional tests with esophageal manometry when this exploration was possible.

Dysphagia was a constant symptom at presentation to the hospital, as well as the main symptom followed in the evaluation of the treatment efficiency. For the assessment of this symptom we used Mellow-Pinkas classification of dysphagia applied to the type of food that cannot be swallowed - grade 0 - No dysphagia, grade 1 - Dysphagia for solids, grade 2 - Dysphagia for semisolid, grade 3 - Dysphagia for solids and liquids grade 4 - Total dysphagia (inability to swallow saliva).

The sizes of the diverticula were appreciated both in centimeters and in degrees according to the Overbeeck classification by corroborating data obtained from the endoscopic exploration and the appearance of the barium contrast imaging. 1 – the small sac that has less than 1 vertebral body in length; 2 –intermediate sac 1-3 vertebral bodies in length; 3 – large sac greater than 3 vertebral bodies in length.

For all the patients surgically treated by cervicotomy, the resection of the diverticulum was performed with myotomy and manual esophageal suture, either single or double layer, or mechanically using a linear stapler. For the patients treated endoscopically, myotomy was performed with creating a wide communication of the diverticulum with the esophagus without resection of the diverticular pouch. A soft, flexible overtube (Cook Medical, Indiana, USA) was used to expose the septum, which was placed over the endoscope, with the short blade placed in the diverticulum and the long blade in the esophagus. After the septum was exposed, it was divided on the midline, from the esophageal lumen to the diverticular pouch, on an average length of 1.5 cm using a Dual knife (Olympus Co., Japan) followed by the closure of the mucosa with clips (2 -5 clips). All patients were clinically and imaged monitored at 3-month intervals during the first post-procedural year.

Study design

For the patients included in the study we studied correlations of patients with symptoms persistence, and to those with reintervention with epidemiological, clinical and the treatment criteria.

Statistical analysis

In comparison with the quantitative data, by the normality of the data, Student's t-test (for two groups with normally distributed data) and Mann-Whitney and Kruskal-Wallis (for data without normal distribution) were used. For the categorical data (synthesized as frequencies and percentages), Fisher exact tests (binary data) and Pearson

Chi-square were used as well as Likelihood Ratio (if 20% of expected frequencies were less than 5). The probability of error of less than 5% ($p < 0.05$) was considered as a significance threshold. The paper also included graphic representations, such as stratified bar type for data synthesized as frequencies and percentages.

RESULTS

Patients included were 29 patients treated endoscopically by myotomy in the Department of Diagnostic and Interventional Digestive Endoscopy of the Regional Institute of Hepatology and Gastroenterology Prof. Dr. Octavian Fodor, Cluj-Napoca and 7 patients surgically treated by resection of the diverticulum associated with myotomy. In the Clinic of General and Esophageal Surgery of St. Mary's Hospital Bucharest. The intraprocedural complications were laminar hemorrhage in three patients during the endoscopic procedure, and one surgically treated patient developed a postoperative hematoma that required drainage. Post-procedural mortality was 0%, and morbidity was 13.88% - five patients (3 patients after endoscopic treatment and 2 patients after surgical treatment).

Persistent postinterventional symptomatology was reported by 11 patients and consisted of the persistence of dysphagia of a lower degree associated or not with the persistence of other symptoms: sialorrhea, regurgitation, nausea, and cough.

We did not observe associations regarding the correlation of the persistence of post-procedural symptomatology with the patients' sex, initial symptomatology or with diverticulitis. (Table 1)

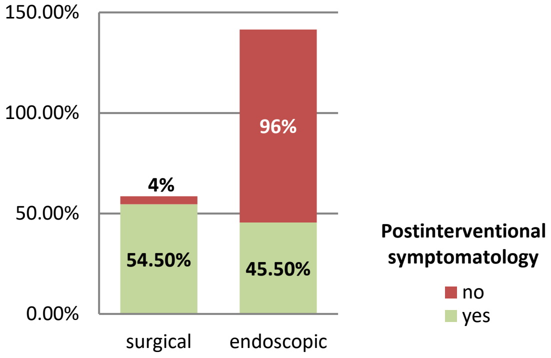
Post-procedural symptomatology we observed only in five patients out of the 29 endoscopically treated and in six out of the seven surgically treated. The statistical association was observed for the type of intervention practiced – endoscopic or surgical treatment (p <0.01) and the persistence of postintervention symptomatology (endoscopic treatment = 45.5%) compared to those without postinterventional symptomatology (endoscopic treatment = 96.0%) – 96% of patients who did not report persistent symptoms had endoscopic treatment. (Table 1) (Figure 1)

Figure 1: Distribution of patients according to the presence of the post-intervention symptomatology to the surgical or endoscopic procedure type



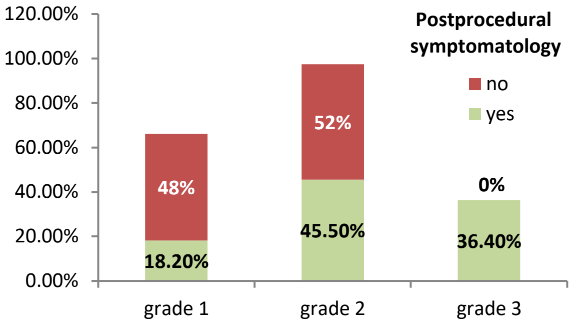
Resistant post-procedural symptoms may be influenced by the type of technique performed: resection of the diverticular pouch or just opening, and association of the myotomy or not. For the patients in the group, the resection of the diverticulum was performed only in the patients treated with open surgery.

The statistical association we observed comparing the percentage of resected Zenker's in patients with persistent postinterventional symptomatology (54.5%) compared to those without postinterventional symptomatology (4.0%) (p <0.01). (Table 1)

Of the 11 patients with postinterventional symptomatology, four patients had grade three diverticula. The correlation of the grade of the diverticulum with the persistence of the post-procedural symptomatology determined a statistical association to the dimension appreciated in degrees according to the Overbeeck classification.

The statistical association was found by correlating the persistence of postintervention symptomatology in patients with grade III diverticula (36.4%) compared with those without postinterventional symptomatology (0.0%) (p <0.01) (Table 1) (Figure 2)

Figure 2: Distribution of patients with post-intervention symptomatology to the dimensional degree of the diverticulum.



In the post-procedural symptomatology dysphagia was the dominant symptom of 10/11 patients – 4 patients had dysphagia grade 1 and 6 patients dysphagia grade 2. The statistical association was observed between the percentage of patients with delayed dysphagia (p <0.01) and those with postinterventional symptomatology (90.9 %) compared to those without postinterventional symptomatology (4.0%). (Table 1) Persistent postinterventional symptomatology was mainly dysphagia.

Post-procedural persistent dysphagia was reported by 11 patients – 5 patients after surgical treatment and 6 after endoscopic treatment, 10 patients had a lower degree of dysphagia than at the initial presentation. Of the 5 patients surgically treated for 3 dysphagia persisted in the first postoperative month and did not require treatment, for the 2 patients with grade 2 dysphagia, one required re-intervention for a hematoma, and another one with esophageal fistula required adequate surgical treatment. We observed a statistical association between persistent dysphagia and surgical treatment (p <0.03), probably due to the small number of patients treated surgically. (Table 2) (Figure 3)

Figure 3: Distribution of patients according to the persistence of postintervention dysphagia to the surgical or endoscopic procedure type.

Post-procedural sialorrhea was reported by four patients. It was not present as a unique symptom but it was always associated with persistent dysphagia. Post-procedural sialorrhea persisted in four patients.

Reintervention was necessary when the persistence of post-procedural symptoms was recorded for 7/11 patients. For the 5 patients treated endoscopically, who required reintervention for the persistence of the symptomatology, an average interval of 22.8 months was observed, while the reinterventions for the 2 patients treated by open surgery happened during the postoperative period. The statistical association was observed in patients who needed reintervention and those with postinterventional symptomatology (63.6%) ($p < 0.01$) (Table 1)

DISCUSSIONS

When comparing the technical and clinical results from the literature on the treatment of Zenker diverticulum, it should be critically emphasized that a direct comparison between studies and results may be inadequate, as the data are neither homogeneous nor standardized in regards of multiple variables. Noteworthy in this regard: symptom collection (dysphagia, dysphagia plus regurgitation, cumulative symptoms), symptom evaluation (objective scores for dysphagia, subjective grading of symptom relief and satisfaction), choice of one or another technique (sequentially, size of the diverticulum, clinical conditions, local policy), the definition of clinical success (total disappearance of symptoms, disappearance with improvement), success and extent of recurrences (after one or more sessions) and variable duration of follow-up (the shortest follow-up programs being reported after endoscopy) flexible, compared to the more recent series of patients treated transorally and with a historical cohort of patients treated surgically).

Patient follow-up included history taking, clinical examination, imaging investigations. Clinical criteria followed were persistence or recurrence of dysphagia and sialorrhea as with other similar studies. [13]

In patients in our group, we found the efficiency of endoscopic treatment of 96% and the whole group of 80%. Most cases published since 1995 demonstrate the efficacy and safety of flexible endoscopy, with clinical success rates between 56% to 100%. [14-15]

The success rate lower than 56% reported in a single series [10] is most likely because the clinical remission was evaluated according to the presence or absence of a group of symptoms and not only dysphagia.

The rate of recurrent symptoms was significantly higher in the surgical group than in the endoscopic group, results different from those reported in other studies where a 39% recurrence rate was found after endoscopic treatment and 0% recurrence in the patients who suffered surgery, probably due to the small number of patients treated surgically. [13]

In the studied group, the persistent postinterventional symptomatology was mainly represented by dysphagia, which is why we consider that in other studies, the efficacy of the treatment should be reported according to the improvement of this symptom. Data from the literature report clinical success increases to 84-100% when the unique series in which success is defined according to dysphagia is taken into account. [9, 11, 15]

As in our study and some other studies, treatment efficacy was reported after a single treatment session, [10, 16] while in other series the success rate was reported after several treatment sessions. [9, 17]

Unlike rigid staple endoscopy, the flexible septotomy technique for the Zenker diverticulum is neither univocal nor standardized. As already mentioned, different cutting techniques can be variably combined with different accessories. The optimal dividing technique is unknown because prospective randomized studies are lacking, and the choice is mainly based on the endoscopist's personal experience and preferences.

In evaluating the success rate of surgery, the most important factor is the subjective evaluation of the swallowing function performed by the patient. Both the primary and revision indications are guided by the patient's symptoms. [18]

Following rigid endoscopic or surgical treatment, persistent septum or residual pouch may still be present on barium contrast examination. Persistent symptoms may be due to other swallowing abnormalities and/or inappropriate myotomy, without correlating the size of the residual pouch and the recurrence of the symptoms. There is a consensus in the literature that the evaluation of treatment efficacy and the need for further treatment must be determined by the patient's symptoms [19, 20] - which we agree with.

Some authors concluded that the presence of a residual diverticulum on an early postoperative esophagogram does not warrant early surgical revision, even when dysphagia persists. In many cases, there may be a slow process of gradual fibrosis of residual dysfunctional cricopharyngeal muscles or atrophy of the remaining diverticular sac over time. In addition, a normal postoperative esophagogram probably cannot predict a good and persistent outcome.

Some authors have reported that only 12.5% of patients with remaining diverticula on the postoperative contrast check develop a recurrence of Zenker's diverticulum. [18]

The approach of redo interventions has changed over time. If in older studies, there is a high percentage of recurrent surgical treatment, [21, 22] we are currently attending an endoscopic revision intervention, and in our study was noted that on a case of redo was necessary to use an endoscopic method after open resection of the Zenker diverticulum for the treatment of dysphagia in case of postoperative stenosis.

Other authors point out the need for classical intervention to resect the residual sac, which, even after a complete myotomy, can be a reason for the persistence of food retention mechanism. This may be the cause of symptoms in patients with prolonged retention of the contrast substance in the pharyngeal pouch and difficult passage into the esophagus, even after complete cricopharyngeal myotomy. [2, 3]

Other authors also suggest that an incomplete cricopharyngeal myotomy may result in higher recurrence rates associated with flexible endoscopy. Ideally, the diverticulum should be reduced to <1 cm. [24]

Incomplete cricopharyngeal myotomy may be visible on radiographs as a cricopharyngeal impression. Hypopharyngeal dysfunction during swallowing of the contrast substance may indirectly suggest incomplete myotomy or recurrent laryngeal nerve injury. On radiographs with contrast substance, pharyngeal dysfunction is suspected if we see contrast substance in the larynx or the tracheobronchial tree. Some authors consider that the persistence of the septum rather characterizes the endoscopic technique and does not predict the failure of the treatment, especially during the immediate postoperative period. [25]

Other authors have tried to evaluate the efficiency of the procedure through manometric studies. Ozgursoy and Salassa reported that a large diverticulum can cause obstruction of the esophageal passage and can lead to high pressure, even if the tone of the upper esophageal sphincter remains normal at manometry. Such a theory leads to the hypothesis that the weak wall of the hypopharynx may play an important role in the development of the diverticulum and leaving the weak adynamic segment of the esophagus creates a favorable environment for recurrence. In addition, the creation of a large cavity after diverticulostomy favors endoscopic techniques over open diverticulectomy on manometric evaluation, because, in a large cavity, small pressures are difficult to record, even if part of the septum remains and this causes dysphagia. [26, 27]

Some studies have shown that post-procedural soluble contrast studies do not correlate with symptoms following endoscopic therapy or relapses and that the second radiological examination, three months after surgery, presents the final functional results, with which we also agree. [8, 25] We also carried out new post-procedural or post-operative radiological studies to exclude a fistula on the seventh postoperative day and in the post-procedural monitoring of patients. Maybe a more accurate assessment of the contrast substance study could be done 3 months after the procedure.

For the patients in the group, we found that the duration of hospitalization in patients with postinterventional symptomatology and those without postinterventional symptomatology was significantly different. The average duration of hospitalization was 2 days for patients without post-procedural morbidity and 7 days for those with post-procedural morbidity comparable to the data in the literature. In our study, the duration of hospitalization of patients with open diverticulectomy was comparable with the data in the literature. [28-30]

The persistence of dysphagia in the 11 patients included in the group usually required reintervention; most of the patients with persistent symptomatology required a reintervention of the same type. Similar studies have also been reported in the literature, most patients who failed the procedure also underwent endoscopic reintervention. [31]

In the patients in the group with bulky diverticula of degree III or larger than 4 cm, the most frequent post-procedural reinterventions were required, 3 out of 4 patients, aspects encountered in other studies. Partial septotomy in the diverticula greater than 5 cm has been proposed by some surgeons, even if the myotomy fails to completely remove the septum and may require more endoscopic interventions. [16, 32, 33]

According to recent literature, some authors recommend the endoscopic procedure for revision surgery as well. The great advantage compared to the open approach is that the endoscopic revision treatment is technically feasible and relatively easy, not more difficult than the primary endoscopic procedure, without an increase in risk. Furthermore, patient satisfaction was higher in those who underwent endoscopic revision surgery compared to those who underwent open surgery revision. [6, 18, 34]

Repeated procedures, in case of therapeutic failure or symptomatic relapse, can be easily and successfully performed by flexible or rigid endoscopy. An additional advantage is that repeated procedures for persistent or recurrent symptoms can be successfully achieved through a transoral (rigid or flexible) approach, while an open approach can be a major technical challenge. [5]

The data from the literature show recurrence rates of about 6% (range 0-22%), with the average recurrence rate of 5% compared to the classical approach, and according to data obtained in our study. [35]

The comorbidities of patients with diverticula included in the group also played a role in the emergence of the situations that required reintervention. [36]

Some authors consider that endoscopic findings tend to decrease over time and that incomplete septotomy is a significant factor for failure rate [37-40], an aspect we have also found.

CONCLUSIONS

Most of the time redo procedures were of the same type, the endoscopic iterative treatment being much easier than the surgical iterative treatment. Undoubtedly, endoscopic treatment has gained more and more confidence even in the field of revision interventions, considering that persistence or recurrence of dysphagia has as substrate an incomplete division of the septum requiring the same type of procedure. Redo procedures were necessary for patients with persistent dysphagia, bulky diverticula, and patients with a high number of comorbidities.

Regression model for predicting the severity of acute poisoning cases by estimating PSS in the Emergency Department

Cristina D. Enache[1], Madalina E. Petran[2,3], Gabriela V. Nitescu[2,4], Coriolan E. Ulmeanu[2,4], Roxana E. Bohîlțea[5], Cristina I. Vivisenco[2,4], Simona Stanca[2,4]

Abstract: *Acute poisonings represent an emergency pathology that associates an increased risk of unfavorable outcomes or death. The mortality rate can be improved by the fast recognition of its severity, which in turn allows a prompt intervention of the medical team. In the practical approach of the case, a standardized measure of predicting the patient's evolution would be necessary, which could be applied quickly to the patient's bed and easy to calculate and apply irrespective of the evaluator. Currently, for acute poisoning cases, Poisoning Severity Score (PSS) is used, a complex and dependable tool that accurately stages the severity of the case but has the disadvantage of being quantified retrospectively. This study presents the development and validation of a linear regression model that can be applied right in the emergency department (ED) and predicts the severity of the case by estimating PSS with an accuracy of 75%. The proposed model uses ten objective and quantifiable variables representing anamnestic, clinical, and biological parameters evaluated in the early stages of the poisoning. The regression was developed in the study group consisted of 62 pediatric patients diagnosed with severe acute poisoning with cardiotoxic agents complicated by cardiogenic shock.*

Keywords: *PSS, regression model, acute poisoning, cardiotoxicity*

INTRODUCTION

Acute poisoning is a global health problem, so preventing mortality is essential in intentional and unintentional exposures. Therefore, predicting the evolution of acutely poisoned patients is of clinical importance because it allows a prompt and adequate therapeutic intervention [1,2].

Like other medical specialties, Toxicology also benefits from classifying the severity of its characteristic pathology, for acute poisoning being used Poisoning Severity Score (PSS). It can be applied to both adults and children, regardless of the type and number of etiological agents involved. For classification, it is necessary to know the complete evolution of the case, considering the most severe clinical and/or paraclinical features recorded during hospitalization. For this reason, the score is quantified retrospectively after the patient's discharge or death. The classification only considers the directly observed signs and symptoms without estimating risks based on parameters such as the ingested dose or the serum/plasma level of the toxicant [2,3].

Predictive scores specific to toxicologic pathology that can be applied in an emergency case are rarely developed, even less so in pediatric patients. Emergency physicians typically use standard scores such as APACHE II/IV (Acute Physiology and Chronic Health Evaluation), SAPS II (Simplified Acute Physiology Score) or SOFA (Sepsis-Related Organ Failure Related). However, these scores do not evaluate the particularities of the clinical examination in a patient with acute poisoning or the characteristics of the toxicant [4].

The exhaustive evaluation that PSS performs using 12 categories of criteria, depending on the systems affected by

the poisoning, makes it valuable and reliable. However, some studies signal some of its disadvantages [2]. Many variables analyzed, some of which have subjective evaluations such as "mild hypotension" or "rare/frequent seizures", make it difficult to quantify, time-consuming, and not consistently reproducible from one evaluator to another [5].

At admission, the examination of the case with acute poisoning may be within normal limits or discreetly modified, yet it may degrade in evolution to the point of requiring advanced therapeutic measures. Therefore it becomes necessary to identify criteria that raise the suspicion of the risk of unfavorable evolution since admission so that the medical team can make the best decisions in handling the case [6].

The importance of PSS for research is undeniable. However, in terms of clinical efficacy, a severity score should quickly assess the prognosis, establish the need for hospitalization and the department's rank where to be cared for, and especially be quickly calculated at the patient's bedside [7].

Considering that PSS is a tool for retrospective assessment of case severity, the premise of this study was to identify those features evaluated from the patient's initial examination that correlates with its subsequent evolution. The study aimed to develop a statistical model that predicts the severity of the case by quantifying these indicators from the emergency department.

METHODS

Study design and selection of study patients

This study is a retrospective analysis of a sample of patients recruited from the Department of Toxicology of the "Grigore Alexandrescu" Emergency Children's Hospital Bucharest. There were analyzed cases of acute poisoning hospitalized between 2014 - 2020, amounting to 7666 patients. Have been researched clinical observation files of the poisoned patients and identified those where the etiologic agent was cardiotoxic, so with a potential evolution to cardiogenic shock, obtaining a group of 1396 patients. After a thorough analysis of the patients at risk, have been selected those that have shown from admission or in evolution signs of cardiogenic shock, obtaining a batch of 62 severe cases.

Each of the 62 pediatric patients enrolled in the study group presented at least one of the following diagnostic criteria for cardiogenic shock: weakly or absent pulse in the major arteries, capillary recoloration time over 2 seconds, low blood pressure, cold, cyanotic or marbled extremities, decrease of diuresis below 1 ml/kg/hour or altered mental status [8,9].

Data analysis protocol

Base data for this research has been collected from the clinical observation files and included the baseline characteristics of patients with poisoning: age and sex; poisoning-related variables, such as the intent of poisoning, type of substance, route of exposure; time-related factors, such as time-lapsed between exposure and examination; and initial vital signs at the ED like heart rate (HR), systolic blood pressure (SBP), body temperature (BT), respiration rate (RR); and AVPU (A-alert, V-verbal response, P-pain response, U-unresponsive) scale of mental status (10,16,17). The collected data also contained admission medical tests and outcome-related variables, such as mortality at ED or after admission.

The work plan included:

(1) Assessment of statistically significant associations between variables: anamnestic, clinical and paraclinical indices, etiology, gender, length of hospitalization, development of complications.

(2) Verifying if the chosen variables can develop a regression model.

(3) Determining the coefficients of the regression model and its validation.

Statistical analysis

The data obtained from the analysis of the clinical cases in the study group were evaluated using the IBM SPSS v20 program, and the results were represented as graphs and tables to identify regression coefficients. The conditions for carrying out a linear regression model were assessed by verifying the existence of gross errors between the recorded values, also if the chosen variables are independent (Durbin-Watson statistical test) or correlated (Pearson test), respectively if there is a statistically significant link between input and output variables (ANOVA test). After all conditions were met, a linear regression model was developed to quantify the relationship between the independent and dependent variables.

RESULTS AND DISCUSSION

PSS is a standardized measure of the acute poisoning severity and is the main objective of the regression model. The usefulness of this model is that it estimates this score at admission, distributing patients into five categories according to the PSS classification.

Of all the variables recorded in the patients' database, ten were selected for having the highest potential to influence the prediction of the PSS [11]. These are intentional poisoning, ECG changes, systolic blood pressure (SBP), bradycardia (according to ages groups), coma, time-elapsed between ingestion and ED examination, transfer from another hospital, etiology represented by pesticides, etiology represented by a combination of beta-blocker with calcium channel blocker, the value of base excess. The values of all the selected variables are recorded in the emergency department after the initial examination [11,12].

In order to verify the model, the batch of 62 selected patients was divided into two samples. One, the derivation group, will be used to make the model, and the other, the validation group, to test the developed model. The number of patients in each group was determined based on Yamane's relationship:

$$n = \frac{N}{1 + N \cdot e^2}$$

where N - the number of patients in the group (N = 62), and e - the chosen marginal error (e = 5%) [13].

Based on the above formula, the group used to develop the model comprises 54 patients, and the rest will constitute the validation group. The eight patients in the test group were chosen at random and had the identification number: 28, 41, 43, 47, 49, 52, 54 and 62.

The development of the regression model was performed in two distinct phases. In the first phase, it is checked if the chosen variables can constitute a linear regression model, while in the second one, the values of the model coefficients are determined.

The following hypotheses were further verified [13]:

If the chosen variables contain gross errors

For this, the linear residues (errors) were determined and checked if their distribution was normal. As can be seen from Table 1, Standard Residuals fall in the range [-3, 3], so it can be concluded that the values used are not affected by gross errors.

Table 1: Determination of linear errors to identify gross errors (Residuals Statistics)

	Minimum	Maximum	Mean	Std. Deviation	N
Predicted Value	2.11	3.46	2.71	0.356	38
Residual	-0.880	1.072	0.000	0.439	38
Std. Predicted Value	-1.686	2.119	0.000	1.000	38
Std. Residual	-1.713	2.085	0.000	0.854	38

[1] If the variables are independent.

This hypothesis was verified based on the Durbin-Watson statistical test (Table 2), which imposes a maximum limit of 3 for independent variables. In our case, the value of the Durbin-Watson coefficient is 2.011.

Table 2: Calculation of the Durbin - Watson coefficient for the selected variables (Model Summary)

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	0.730	0.797	0.173	0.514	2.011

(2) If the variables are correlated

For this, the Pearson coefficients between the independent and the dependent variable were calculated, and because the value of these coefficients does not exceed the threshold of 0.59, it was concluded that there is no individual statistical correlation.

(3) If there is a statistical link between the independent and the dependent variables

This hypothesis was verified based on the ANOVA test, which produced a coefficient p <0.05 (Table 3), meaning that the statistical significance of the proposed regression model is significant. Therefore there is a statistically significant link between the independent and the dependent variables.

Table 3: ANOVA test applied for the chosen variables

Model	Sum of Squares	df	Mean Square	F	Sig.
Regression	4.685	10	0.469	1.774	0.015
Residual	7.131	27	0.264		
Total	11.816	37			

Because all the hypotheses were fulfilled, a linear regression model was made in the second phase, and the coefficients related to this model were determined (Table 4). In this case, all the coefficients are statistically significant for the model (the value of p <0.05) and have the values from the table.

The regression model developed is represented by equation below:

$$\text{PSS \_estimated} = \text{IP} \cdot 0.402 + \text{ECG} \cdot 0.097 - \text{SBP} \cdot 0.004 + \text{Coma} \cdot 0.495 + \text{Brad} \cdot 0.146 + \text{Texp} \cdot 0.001 - \text{Referral} \cdot 0.086 + \text{BE} \cdot 0.019 + \text{Pes} \cdot 0.499 + \text{BBCC} \cdot 0.565 + 2.407 \quad (1)$$

where: IP – intentional poisoning (0/1), ECG – ECG changes at presentation (0/1), SBS – systolic blood pressure at presentation (mmHg value), coma – coma at presentation (0/1), Brad – Bradycardia (0/1), Texp – time between exposure and examination (minutes), Referral (0/1), BE –

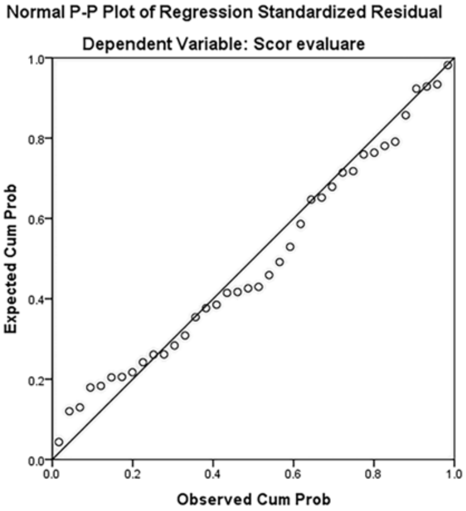
base excess at presentation (value mmol / l), Pes – Pesticides (0/1), BBBC – beta-blocker and Ca channel blocker (0/1), constant = 2.407.

Table 4: Determination of the coefficients related to the linear regression model

Variable	Linear regression model coefficients		Standardized coefficients	t	Sig.
	B	Standard Error	Beta		
Constant	2.407	0.414		5.809	0.000
Intentional poisoning	0.402	0.237	0.335	1.699	0.001
ECG modified	0.097	0.245	0.083	0.396	0.006
SBP (mmHg)	-0.004	0.005	-0.196	-0.777	0.044
Coma	0.495	0.276	0.344	1.791	0.035
Bradycardia	0.146	0.200	0.128	0.732	0.041
Time-lapse between exposure and examination (min)	0.001	0.000	0.234	1.433	0.013
Referred patient	-0.086	0.206	-0.076	-0.420	0.048
Pesticide	0.499	0.296	0.302	1.683	0.004
Base excess	0.019	0.032	0.118	0.590	0.050
Beta-blocker and Ca channel blocker combination	0.565	0.304	0.342	1.857	0.047

In order to avoid an additional phase of interpreting the results and obtain a quick estimate of the prognosis, in the development of the model, it was considered that the value range of the estimated PSS variable should be identical to that of the standard PSS variable. This fact led to the appearance of subunit coefficients with three decimals and, therefore, a complex function. We consider that this compromise is acceptable to keep the easy interpretation of the data. The practical calculation can be performed with the help of the Excel program.

Figure 1: Visual representation of the regression model



°: *PSS registered at the patient's discharge or death (training data)*

—: *PSS estimated using the proposed regression model*

Their similar appearance can be noticed by overlapping the estimated PSS graph and the registered PSS graph (Figure 1).

The validation of the model was done starting from the degree of correlation between the independent and dependent variables. Thus, based on the values in Table 5 below, we conclude:

- there is a high degree of correlation between the independent and dependent variables R = 0.730.
- 79.7% (R2 = 0.797) from the variation of the dependent variable is generated by the independent variables chosen in the model. The remaining 20.3% is influenced by other variables that could not be identified in the present study.

Table 5: Checking the correlation between the independent and the dependent variable

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	0.730	0.797	0.173	0.514	2.011

Further, to have a quantitative evaluation of the developed model, equation 1 was applied to the sample of eight patients in the test group. Their input data are summarized in Table 6.

Following the application of the regression model developed, in 6 of the 8 cases tested, PSS was accurately predicted (Table 7). This results in a success rate of 75%. It can be concluded that the developed model successfully predicts PSS, impacting choosing the optimal therapy for each patient [14].

Table 6: Input data of the 8 patients in the test group

ID	IP	ECG	SBP	Coma	Bradycardia	T_{exp}	Referral	Pesticide	BE	BBBC
28	0	0	74	0	0	40	1	0	-4.6	0
41	0	1	95	0	0	120	1	0	1	0
43	1	1	120	0	1	30	1	0	-2	0
47	0	0	90	0	0	300	1	1	-10	0
49	1	1	115	0	1	1440	0	0	1.4	0
52	0	0	100	0	0	60	0	0	-2	1
54	0	1	100	1	0	180	1	0	-1.1	0
62	1	1	147	0	0	120	0	0	11	0

Table 7: The results obtained in the test group following the application of the regression model

Estimated PSS	Rounded PSS	Recorded PSS	PSS differences
1.9416	2	2	0
2.069	2	2	0
2.451	3	3	0
2.3	2	4	2
2.7626	3	2	1
2.54	3	3	0
2.5101	3	3	0
2.539	3	3	0

Due to the subunit coefficients of the identified variables, the application of the model could be time-consuming and prone to errors. The alternative is represented by a multicriteria analysis derived from the proposed regression model, which would reduce the number of variables used and create a faster calculation template for estimating the PSS. However, its accuracy would decrease, being a compromise between the complexity of the regression model and precision [15].

There are numerous studies in the literature, but most of them performed on the adult population, which propose various scores to predict the severity or mortality of cases of acute poisoning. A Korean team (Han et al.) published a recent article proposing a new score for predicting poisoned patients mortality in the ED [10]. The developed template uses a hybrid approach where the model coefficients are divided into categories, and their value is standardized to facilitate the total calculation. However, the model requires an additional phase of interpreting the results and, in addition, only estimates the risk of mortality without making assessments about the cases' evolution.

CONCLUSIONS

The present study aimed and succeeded in developing a linear regression model that uses both toxicant-related characteristics and patients' physiological features in the emergency department, in order to predict Poisoning Severity Score with an accuracy of 75%, in the early stages of acute poisoning with cardiotoxic agents complicated by cardiogenic shock.

The proposed regression model can be the basis of multicriteria analysis, much easier and faster to apply by the examining physician, and which should be a valuable tool for predicting the patient's outcome in the emergency department.

Although the present study was carried on a small sample of patients, the applied methodology has the advantage of a smooth transition to a larger group. The accuracy of the model can be further improved by the increase of the training lot.

Relationship between pregnancy and sense of taste

Nima Sadeghi[1], Habibeh Farazdaghi[2], Parastoo Parandoosh[3], Parisa Dehghani[4], Mandana Khatibi[4]

Abstract: *Background: The change in taste is common for pregnant women. This study aimed to assess the sense of taste in pregnant women in comparison with non-pregnant women.*

Methods: A cohort study was conducted on 120 healthy women. The test group (n=60) included pregnant women presenting to a hospital for pregnancy care in their first, second and third trimesters. Control group (n=60) included healthy non-pregnant women presenting to the same center. The groups were matched in terms of age, marital status and oral hygiene. Assessment of sense of taste was done for two groups using sucrose, sodium chloride and citric acid solutions for perception of sweetness, saltiness and sourness. Serial dilutions of sucrose and sodium chloride solutions were prepared in 1.0, 0.1 and 0.01mM concentrations. Serial dilutions of citric acid were prepared in 3.2, 0.32 and 0.032M concentrations. Data were analyzed using SPSS version 17 and chi square test.

Results: Forty-four non-pregnant (73.3%) and 26 pregnant (43.3%) women gave wrong answer to 0.01mM sucrose solution and this difference wasn't statistically significant (p=0.07). One individual in each group (1.7%) gave wrong answer to 0.1 and 1mM concentration of sucrose. This difference wasn't statistically significant (P=0.9). Wrong answers in the two groups and among the three trimesters weren't significantly different for sodium chloride and citric acid (P=0.9). The difference among pregnant women in the three trimesters wasn't significant for any concentration or tested solution (P=0.9).

Conclusion: The sweet taste threshold decreases during pregnancy but the perception threshold for saltiness and sourness remains unchanged.

Keywords: *pregnancy; taste; taste threshold*

INTRODUCTION

Change in the sense of taste is a common complaint of pregnant women and can result in alterations in their nutritional regimen [1]. Nutrition of mother during pregnancy is a critical factor in health of mother and fetus. Poor quality of nutrition during pregnancy can lead to nutritional deficiencies, weight gain, and increased risk of pregnancy diabetes, high blood pressure and problems during delivery [1]. The pregnant women in their second trimester have higher sugar cravings [2]. The changes in sense of taste have a relatively high prevalence in pregnant women (26%) and most pregnant women in their study showed increased sensitivity to bitterness and decreased sensitivity to saltiness [3]. The sense of taste changes during pregnancy especially in the first trimester [4]. Change in sense of taste can serve as a protective mechanism since pregnant women have less craving for bitter foods, which often contain toxic agents and by doing so, the fetus is protected against toxic nutrients [5].

The mechanism of change in sense of taste during pregnancy has yet to be fully understood. However, hormonal alterations as the cause of changes in taste during pregnancy [6]. Changes in nervous system are also a suggested mechanism for change in sense of taste during pregnancy [7].

The studies on changes in sense of taste during pregnancy have yielded controversial results and discussed that this controversy might be attributed to different methodologies

of studies and methods of assessment [8]. Also, change in sense of taste may be variable in different trimesters and it has been shown that alternations in sense of taste have the highest prevalence in the first trimester and decrease later in the course of pregnancy. The sense of taste returns to normal after delivery [3]. This study aimed to compare the sense of taste in pregnant women in different trimesters in comparison with non-pregnant women in the Mirzakoochak Khan Hospital, Tehran, Iran.

METHODS

Research design

This historical cohort study was conducted at the Gynecology and Obstetrician Department of Mirzakoochak Khan Hospital Tehran, Iran.

Research subjects

A total of 120 pregnant and non-pregnant women (60 pregnant and 60 non-pregnant women) were included into the study. The sample size was calculated based on a pilot study conducted on 10 pregnant and 10 non-pregnant women; the difference in percentage of wrong answers between the two groups was 20%. Considering the confidence interval of 90% and study power of 80%, sample size was calculated to be 60 in each group (a total of 120 in the two groups) [9].

Pregnant women comprised the test group and were selected among those presenting to Gynecology and Obstetrician Department of Mirzakoochak Khan Hospital for routine pregnancy care. Pregnancy of these patients had been confirmed by urine and blood tests.

The test group (n=60) included pregnant women presenting to a hospital for pregnancy care in their first, second and third trimesters.

The control group included non-pregnant women who were selected among those presenting to the same hospital for routine checkup and matched the test group in terms of age, marital status, oral hygiene and use of prosthetic or orthodontic appliances. The inclusion criteria were absence of systemic diseases, no history of sensory disturbances in the oral cavity, no smoking, no drug intake (except for vitamin supplements), no history of radiotherapy or chemotherapy, absence of mouth dryness [10] and absence of nausea and vomiting of pregnancy.

Oral hygiene measurements

To assess oral hygiene of participants, the Turesky-Gilmore-Glickman modification of Quigley Hein index was used [11]. Disclosing tablets were used to quantify plaque accumulated on buccal and lingual surfaces of teeth. Calculated plaque index ≤2 indicated good oral hygiene and plaque index >2 indicated poor oral hygiene.

Taste perception test

The sense of taste in participants was assessed according to the method described by Saluja et al. [12]. Three serial dilutions (1/2 log concentration) of sucrose, sodium chloride and citric acid solutions were prepared to assess the perception of sweetness, saltiness and sourness. Sodium chloride and sucrose solutions were serially diluted to obtain 1.0, 0.1 and 0.01mM concentrations. Citric acid was serially diluted to obtain 3.2, 0.32 and 0.032M concentrations. The solutions were diluted using distilled water. Participants were requested to refrain from eating and drinking for one hour before testing. They were asked to rinse their mouth 10 seconds prior to testing. Next, they were requested to taste 5mL of each solution for 10 seconds and then spit it out (starting from the lowest concentration). Participants were asked to rinse their mouth in-between tastings. Each test took 5-10 minutes in each individual and a minimum interval of 30 seconds was allowed between tests. Minimum concentration of each solution perceived by each participant was recorded. Participants were classified for their taste perception into two groups of correct and incorrect taste perception [12].

Assessment of taste perception was carried out between 9-11 a.m. every morning in a relaxed position under the same conditions for all patients.

Statistical analysis

Data were analyzed using SPSS version 17 (SPSS Inc., IL, USA) and the data were compared between the test and control groups using chi square test. A $p<0.05$ was considered statistically significant. Because the study was a qualitative research based answer of pregnant women, the Chi-square should be used for statistically significantly results.

Ethical clearance

Both test and control group subjects were thoroughly informed about the study and signed informed consent forms prior to participation in the study. Participants were ensured about the confidentiality of their information. The study protocol was approved in the Ethics Committee Of Dental Branch, Islamic Azad University (code: IR.IAU.DENTAL.REC.1395, 22).

RESULTS

A total of 120 participants including 60 pregnant and 60 non-pregnant women were evaluated. The mean age was

25.1±2.6 years in non-pregnant and 26.4±3.3 years in pregnant women. The two groups were not significantly different in terms of age (P>0.05). In terms of oral hygiene, in the group of non-pregnant women, 48 had well and 12 had poor oral hygiene. In pregnant women, 50 had well and 10 had poor oral hygiene. The difference in this regard between the two groups was not significant (P>0.05).

Table 1 shows the frequency of correct and incorrect taste perceptions in the two groups based on the concentration of sucrose solution tested. As seen in Table 1, in the group of non-pregnant women, 44 (73.3%) had wrong taste perception for 0.01mM concentration of sucrose; this rate was 43.3% (n=26) in pregnant women. According to chi square test, this difference between the two groups was statistically significant (P<0.05). One participant in each group (1.7%) had wrong taste perception for 0.1mM concentration of sucrose and the two groups were not significantly different in this respect (P=0.9). One participant in each group (1.7%) had wrong taste perception for 1.0 mM concentration of sucrose and the two groups were not significantly different in this respect (P=0.9).

Table 1: The frequency distribution of taste perception of participants in the two groups based on the tested concentration of sucrose

Group/Sucrose concentration (mM)	0.01		0.1		1	
	Correct	Wrong	Correct	Wrong	Correct	Wrong
Non-pregnant	16 (26.7%)	44 (73.3%)	59 (93.3%)	1 (1.7%)	59 (93.3%)	1 (1.7%)
Pregnant	34 (56.7%)	26 (43.3%)	59 (93.3%)	1 (1.7%)	59 (93.3%)	1 (1.7%)
P value	P<0.05		P=0.9		P=0.9	

Table 2 shows the frequency distribution of participants in terms of taste perception of different concentrations of sodium chloride. As seen in Table 2, taste perception of different concentrations of sodium chloride was not significantly different between the two groups of pregnant and non-pregnant women (P=0.9).

Table 2: The frequency distribution of taste perception of participants in the two groups based on the tested concentration of sodium chloride

Group/Sodium chloride concentration (mM)	0.01		0.1		1	
	Correct	Wrong	Correct	Wrong	Correct	Wrong
Non-pregnant	14 (23.3%)	46 (76.7%)	59 (93.3%)	1 (1.7%)	59 (93.3%)	1 (1.7%)
Pregnant	15 (25%)	45 (75%)	58 (96.6%)	2 (3.4%)	58 (96.6%)	2 (3.4%)
P value	P=0.9		P=0.9		P=0.9	

Table 3 shows the frequency distribution of participants in terms of taste perception of different concentrations of citric acid. As demonstrated in Table 3, taste perception of different concentrations of citric acid was not significantly different between the two groups of pregnant and non-pregnant women (P=0.9).

Table 3: The frequency distribution of taste perception of participants in the two groups based on the tested concentration of citric acid

Group/Citric acid concentration (mM)	0.01		0.1		1	
	Correct	Wrong	Correct	Wrong	Correct	Wrong
Non-pregnant	1 (1.7%)	59 (93.3%)	59 (93.3%)	1 (1.7%)	60 (100%)	0
Pregnant	0	60 (100%)	59 (93.3%)	1 (1.7%)	59 (93.3%)	1 (1.7%)
P value	P=0.9		P=0.9		P=0.9	

Comparison of taste perception of women in the three trimesters for citric acid, sucrose, and sodium chloride showed no significant differences (P>0.05, Table 4).

DISCUSSION

The change in taste is common for pregnant women. This study aimed to assess the sense of taste in pregnant women in comparison with non-pregnant women. Forty-four non-pregnant (73.3%) and 26 pregnant (43.3%) women gave wrong answer to 0.01mM sucrose solution and this difference wasn't statistically significant (p=0.07). One individual in each group (1.7%) gave wrong answer to 0.1 and 1mM concentration of sucrose. This difference wasn't statistically significant (P=0.9). Wrong answers in the two groups and among the three trimesters weren't significantly different for sodium chloride and citric acid (P=0.9). The difference among pregnant women in the three trimesters wasn't significant for any concentration or tested solution

(P=0.9).

Table 4: The frequency distribution of pregnant women with correct taste perception of sucrose, sodium chloride and citric acid in the three trimester

Trimester/Solution	Sucrose			Sodium chloride			Citric acid		
	1	2	3	1	2	3	1	2	3
First trimester (n=20)	9	11	0	5	15	0	0	20	0
Second trimester (n=20)	13	6	1	6	13	1	0	19	1
Third trimester (n=20)	12	8	0	4	15	1	0	20	0
P value	P=0.9								

Proper and healthy nutrition plays a key role in a successful pregnancy [12]. Increased appetite is a common finding during pregnancy [14,15]. However, change in sense of taste and nutritional problems have been commonly reported by pregnant women [16]. This study compared the sense of taste of pregnant and non-pregnant women using different concentrations of sucrose, sodium chloride and citric acid solutions. These solutions were chosen for this study since they have no adverse effect on the mother and fetus.

Electrogustometric evidence shows that taste threshold increases with age. In other words, aging decreases the sense of taste [17]. These changes often commence at the age of 60 years in areas innervated by the chorda tympani and glossopharyngeal nerves and at the age of 70 years in areas innervated by the greater petrosal nerve [17]. Since the current study was conducted on 20 to 30 year-old women, the effect of age on sense of taste was not significant.

The current results revealed that the taste threshold of sucrose (sweetness) in pregnant women was lower than that in non-pregnant women. Similarly, the reduction in taste threshold of all tastes including sweetness in pregnant women [18]. Saluja et al, [12] also reported deceased taste threshold for sucrose in pregnant women. This change in taste has been attributed to hormonal changes during pregnancy. The changes in taste threshold of women during menstruation cycle and showed hyper-sensitivity to taste prior to ovulation and decreased sensitivity to taste after ovulation [19]. Since the sense of taste was found to be constant in males, such alternations in sense of taste especially for sweetness in women were attributed to female sex hormones and their alterations. They explained that increased sensitivity to taste prior to ovulation is probably attributed to high level of estrogen and decreased sensitivity to taste after ovulation is probably attributed to a combined function of estrogen and progesterone.

Our study only found a significant difference in taste of sweetness between pregnant and non-pregnant women while Kolbe et al. [20] reported higher taste threshold for all four main tastes in pregnant women. Also, Kuga et al. [4] reported increased taste threshold in pregnant women particularly in the first trimester. Difference between their results and ours may be explained by racial and ethnic differences between populations and different methodologies of the studies since Kuga et al. [4] did not perform an actual testing on participants and only questioned the participants verbally. The accuracy and reliability of this method (self-report) is somehow questionable. The method used by Kolbe et al. [20] was different from that in our study. Also, use of different concentrations of solutions can yield different results.

We did not find any significant difference between pregnant and non-pregnant women in terms of tasting saltiness, which was in line with the results of Saluja et al [12]. They reported that pregnancy does not affect on taste perception of saltiness. However, our results in this regard were in contrast to those of Brown and Toma [21], Hayes et al, [6] and Ochsenbein-Kölbleet al [18] since the afore-mentioned studies reported decreased taste threshold or higher craving for saltiness during pregnancy. These differences in the results of studies may be attributed to the use of different solutions with variable concentrations.

In our study, the difference between the two groups in terms of perception of sourness was not significant, which was in agreement with the results of Saluja et al. [12] who also reported that taste perception for sourness does not change during pregnancy. However, the some studies indicated that craving for sourness was different between non-pregnant women and those in the first, second and third trimesters of pregnancy. Also, Kolbe et al. [20] and Kuga et al. [4] indicated a change in perception of sourness in pregnant women. Racial, ethnic and geographical differences can all affect the nutritional habits of individuals and their perception of tastes such as sourness. Also, individual and genetic differences (variations in chemical receptors) can affect the sense of taste [22, 23]. It appears that each individual has their own gustation perception, and nutritional habits of individuals can also affect their taste threshold.

In general, in a healthy state, gestation of pregnant women is altered in a such a way to protect the health of mother and fetus. Changes in sense of smell of pregnant women also protect them against harmful chemicals. Changes in sense of taste during pregnancy enable consumption of a wider range of electrolytes and nutrients [20]. These changes include increased sensitivity to bitterness in the first trimester as a protective mechanism against toxins and increased craving for salty, sweet and sour foods in the second and third trimesters in order for the mother to consume a wide variety of nutrients required for the health of fetus [6]. Several physiological, psychological and social factors control nutritional habits of individuals. Psychological, physiological and behavioral factors can also affect the nutritional choice and consumption of food by pregnant women.

Several factors including oral hygiene, smoking, alcohol use, drug intake, systemic diseases and history of chemotherapy and radiotherapy may affect the sense of taste of individuals. Thus, in this study, the two groups were matched in terms of oral hygiene, and the other afore-mentioned factors were set as our exclusion criteria in order to eliminate their confounding effect on the results. This was strength of our study and has not been done in previous studies. One limitation of our study was that taste of bitterness was not evaluated. Quinine hydrochloride is often used for assessment of taste perception of bitterness. However, due to possible adverse effects of this agent on the fetus, we did not use it in our study. Future studies with larger sample sizes are required to confirm the results of this study.

CONCLUSION

The results of this study showed that the taste threshold of sweetness decreased during pregnancy but no difference was detected in taste threshold of saltiness or sourness between pregnant and non-pregnant women.

Renal angiomyolipoma – a short review of the literature

Lucian Iorga[1], Raluca S. Costache[2,3], Radu Anghel[1], Ioana Bratu[4], Maria Manea[5], Dragos Marcu[1,2]

Abstract: *Renal angiomyolipomas (AML) are the most common benign renal tumors. By containing an important amount of fat tissue they are easily identifiable on CT and MRI images, thus no biopsy should be needed for a diagnosis. However there is a small percentage of AMLs that have very little fat tissue and are very difficult to differentiate from renal cell carcinoma. Along fat tissue, they also contain smooth muscle and blood vessels. Renal AMLs can occur as a sporadic finding, or more frequently in association with tuberous sclerosis complex (TSC) or pulmonary lymphangioleiomyomatosis (LAM). These tumors are usually an incidental finding on imaging tools, but sometimes a serious presentation is rupture and hemorrhage, which can easily evolve to shock. Therapeutical management vary from active surveillance to surgical removal, and it needs to be individualized for every patient and according to the clinical presentation.*

Keywords: *renal angiomyolipoma, tuberous sclerosis, therapeutical management*

INTRODUCTION

Renal AMLs are the most common benign renal tumors, having a reported prevalence of 0.2-0.6%, with a female to male ratio in favor of females. Because of the increase use of imaging tools and the advances in imaging methods the frequency of detection in the general population is increasing. AMLs are more frequently associated with patients with tuberous sclerosis complex (TSC), having been reported in 75-85% of cases with renal lesions and in 49-60% in TSC patients overall [1-2]. In cases of lymphangioleiomyomatosis (LAM), aproximately 45-60% of patients tend to have renal AMLs, usually being multiple and bilateral [3-4]. Even though the prevalence of AMLs is low among patients who do not have TSC or LAM, combined with the fact that the prevalance of sporadic AML exceeds the estimated birth incidence of TSC or LAM, it makes it more common [5]. AMLs are a member of a group of tumors called neoplasms with perivascular epithelioid differentiation, arising by clonal proliferation of epithelioid cells distributed around blood vessels [6, 7].

Histological findings

Renal AMLs are made of smooth-muscle-like cells, adipocyte-like cells, and epithelioid cells, with the three types of cells appearing to be derived from pericytes, fact suggested by the fact that these cells express perycyte markers [8].

AMLs are classified in two major histological groups. The most common histological variant is the classic one, having abnormally thick-walled vessels that lack a well-developed internal elastic lamina and varying amounts of spindle smooth-muscle-like cells and adipose tissue. However, some tumors consist solely of one component, while the other elements are present in very small amounts. In the classic variant epitheliod cells are rare, making up less than 10% of cells in this type of AML [9]. Classic AMLs are bening but, there are cases with local invasion into the perirenal fat, and in very rare ocasions into the collecting system, renal vein, or inferior vena cava and right atrium. The epithelioid variant, unlike the classic one can undergo malignant transformation. There is no consensus on the percentage of epithelioid cells that is required to make a diagnosis of the epithelioid variant, but studies sugest that a percent higher than 70% of epithelioid cells, a tumor size >7 cm, vascular invasion, ≥2 mitotic figures per 10 high-power fields, atypical mitotic figures and necrosis suggest an increased risk for malignant transformation [10].

Epithelioid cells are differentiated by their abundant eosinophilic and granular cytoplasm.

Epithelioid AML has less fat tissue than the classic variant, making it more difficult to diagnose by imaging, frequently resembling and be misdiagnosed as renal cell carcinoma.

In addition to these two major histological groups, there is a rare variant, characterized by solid and cystic areas, called angiomyolipoma with epithelial cysts. It is a benign lesion with no evidence of metastasis or recurrence following surgical excision [11]. The three variants are differentiated from each other only after biopsy.

DIAGNOSIS

Clinical presentation

Commonly patients are asymptomatic at the time of diagnosis, AMLs being an incidental finding. This is explained by the increasing use of imaging tools and the advances in imaging technology [12].

Among symptomatic patients, the most common sign is flank pain, followed by a palpable mass, haematuria, anaemia, urinary tract infection, or an impaired renal function. In a study conducted by Koo et al on 129 patients, 75% of them were asymptomatic [13]. Regarding symptomatic patients, Bissler et al found that out of the 32 sypmtomatic patients included into their study 20 had flank pain, 7 had hematuria and 2 had spontaneous rupture [14].

A serious form of presentation, seen in less than 15% of cases, is spontaneous retroperitoneal haemorrhage, which can lead in one third of patients to shock. Therefore, risk of a life-threatening bleeding is the main clinical concern in a patient diagnosed with AML [12].

The epithelioid variant of AMLs can undego malignant transformation. Though rare, it is characterized by local aggressivness, lymphadenopathy, and distal metastases. The larger the tumour, the more likely it is to spread, acting like a veritable retroperitoneal tumor [15-19] and can produce secondary hydronephrosis that must be drained with a double J stent [20, 21].

AMLs tend to be more aggressive in patients with TSC or LAM, thus symptomatic patients are more commonly found in these cases. It is important to screen patients diagnosed with AML for TSC and LAM. Patients with multiple, bilateral, or larger (≥4 cm) are at higher risk for TSC and the tumors are usually diagnosed at an early age.

Imaging features

By containing fat tissue AMLs are very easily diagnosed using imaging tools. However, in cases of hemorrhage, calcification, necrosis or low fat content the diagnosis becomes a challenge. A recent article classified renal AMLs as fat-rich, fat-poor, or fat-invisible, based on the amount of fat detected on imaging studies [22].

A hyperechoic lesion, resulting from a combination of fat, blood vessel, and muscle contents, with a posterior acoustic shadow, due to the multiple tissue interfaces is the classical appearance of an AML rich in fat tissue on ultrasound [23]. The echogenity of the tumor depends on the percentage of fat tissue in the AML, usually being the same as or greater than that of the renal sinus, but as the amount of fat gets lower, the echogenity decreases.

AML low in fat content are usually a mixture of hyperechoic and isoechoic lesions compared with the renal parenchyma, while a fat-invisible AML is homogenously isoechoic with it. In these cases it is hard to differentiate renal cell carcinoma from an AML on ultrasound [22, 24].

Computed tomography (CT) scan is recommended when hyperechoic lesion is found by ultrasound, having excellent sensitivity, specificity, and reproducibility regarding renal masses. Computed tomography can identify macroscopic fat in AML as low-density area of −10 HU or lower. Fat-poor AMLs are heterogeneously isoattenuating or hyper-attenuating, but on the other hand, fat-invisible AMLs appear homogenously hyperattenuating. Contrast-enhanced CT is not necessary for diagnosing fat-rich AML but shoud be performed where there is a risk for tumor bleeding, to identify the tortuous vessels, before therapeutic embolization can be scheduled [22, 25].

Kidney AML can be very similar with renal cell carcinomas and hemorrhagic cysts on the MRI images, thus fat suppression techniques may be helpful in differentiate them from each other [23]. As in computed tomography imaging, contrast enhanced MRI has a limited role in the diagnosis of AML.

In some cases, especially in fat-invisible AMLs, when both CT and MRI images are inconclusive and we cannot differentiate AMLs from renal cell carcinomas on imaging alone, percutaneous renal biopsy is recommended to avoid unnecessary treatment.

TREATMENT

AMLs being an incidental finding on imaging tools in asymptomatic patients, implies that a small percentage of cases requires active treatment.

The current guidelines regarding AMLs recommend active treatment in well-selected cases, such as: symptomatic tumours, the presence in women of childbearing age, poor access to follow-up or emergency care and large masses, but a size threshold remains controversial (historically a size greater than 4 cm was considered an indication for surgery).

Active surveillance

If the indication for active treatment are not present, all patients with AML should undergo routine monitoring by imaging to assess stability [26]. Patients with tumors less than 2 cm should do renal ultrasound every 3 to 4 years and those with masses measuring 2 to 4 cm should undergo ultrasound monitorisation every year. Patients with masses larger than 4 cm in diameter, who do not undergo surgery should be assesed, by ultrasound or CT every 6 months, and if stable, anually. The same with patients with epithelioid variants. Patients who have had surgical removal of an epithelioid AML, at high-risk for malignant transformation, should have whole-body CT six months after surgery and yearly thereafter for at least five years [27].

Embolization

Selective embolization of the renal artery is the preferred treatment for patients with life-threatening retroperitoneal hemorrhage. Embolization can be performed preoperatively to reduce the difficulty and complications of the surgical removal. It has a relatively high percentage of side effects including: fever, flank pain, leucocytosis, nausea, and vomiting within the first three days after the procedure, but nothing that cannot be managed conservatively. Other rare complications include non-target embolization of normal parenchyma or renal infarction [28,29]. Altough it is a generally well-tolerated procedure, it has a risk of regrowth and repeated haemorrhage after embolization [30].

Surgical excision

Partial or radical nephrectomy can be used to treat renal AMLs, being the only treatment that completely removes the renal mass. Current guidliness recommend that nephron-sparing surgery should always be performed whenever possible, being even more important in patients with TSC or LAM, because of the multifocality of the disease in this group of patients and the higher risk of recurrence. Radical nephrectomy should be used only in selected cases, with large masses and a high risk of malignant transformation, or when other treatment options are not viable. Sometimes, in an emergency setting, a radical nephrectomy can be a life-saver [18].

Minimal invasion techniques

Cryoablation and percutaneous radiofrequency ablation can be used as an alternative to embolization or surgery. Different studies show good efficacy with minimal complications, very few therapy sessions and no recurrences, but these minimal invasion techniques should be used on small (1-3 cm in diameter) and asymptomatic lesions [31].

Medical treatment

mTOR inhibitors, such as Sirolimus or Everolimus, decreases the risk of tumor progression and reduces the size of the tumor, especially in patients with TSC or LAM., but the use of these drugs in sporadic LAMs is still debatable. Recent guidelines recommend the use of mTOR inhibitors in patients with progressive renal LAMs greater than 3 cm in asymptomatic patients with TSC or LAM as the first line of treatment. Other treatments are required in case of secondary complications, such as cardiovascular diseases [32-36] or infections [37, 38].

DISCUSSIONS

A Japanese study, using a population-based ultrasound screening, included 18,000 healthy adults, and found that 0.1 percent of men and 0.2 percent of women had renal AML [39]. Rule et al stated that renal AMLs are more common seen in middle aged women, compared to men, findings supported by Koo and his team in their research on a group of 117 patients with sporadic AML, that found that 92% of patients were women with a mean age of 52 years old [16, 40].

Ewalt et al in their longitudinal study on 60 children with TSC found that renal AMLs were present in 48% of boys and 60% of girls at a mean age of 7 years old and in 76% of boys and 83% of girls at a follow-up age of 10 years old, suggesting that the prevalence of renal AMLs in patients with TSC is increasing with age [41].

In their paper on diagnosis and management of renal angiomyolipoma, Seyam and his colleagues included 60 patients with renal AMLs with a median age of 45 years old, from which 43 were females. Half the patients presented with flank pain and only 13 had hematuria. They screened patients for TSC and found this disease in 14 patients. More than half the patients were followed up expectantly, the mean size of the tumor being 4 cm in diameter, suggesting that the majority of patients with AMLs should undergo routine monitoring to assess stability. 29 patients needed active treatment to control bleeding and relieve pain or because of the risk of malignant transformation. Tumors that are larger in size have a higher risk of bleeding, the mean size of masses in which retroperitoneal hemorrhage was discovered was approximately 11 cm. Patients were followed up for a mean of 4 years and the lesions grew an average of 5 cm for TSC patients and less than 1 cm for the sporadic group, suggesting that patients with TSC are at a higher risk of progression. Furthermore, patients whom had TSC compared with the sporadic group were younger at presentation (26 versus 49 years old), had bigger renal masses (19 cm compared with a mean of 4 cm) and had multiple or bilateral lesions [42]. Similar findings were stated in a smaller group study conducted by Nelson et al (336 patients with 19% having TSC). The patients within the sporadic renal AMLs group were older (mean 52 years old compared with 30 years old), had smaller AMLs (mean 5 compared 9 cm), and were much less likely to have both multiple lesions (13% compared with 97%) and acute hemorrhage (14% compared with 44%) [43].

Some authors recommend that renal AMLs measuring 4 to 8 cm in diameter should be observed, if asymptomatic and close follow-up can be achieved [44, 45].

Bissler and his colleagues in their paper on mTOR inhibitors included 118 patients with AMLs, 5 of which were sporadic, the rest being in correlation with TSC. The target of at least 50 percent reduction in the total volume of the mass was achieved in 42% of the patients treated with everolimus compared with none of the patients treated with placebo, with a median response time of 3 months. Progression of AMLs was significantly more common in the placebo group (21%

compared with 4% in the mTOR inhibitors treated group) [46].

mTOR inhibitors treatment can be used to reduce the volume of tumors so the patients can benefit from a nephron-sparing surgery, fact stated in Staehler's paper on „Nephron-sparing resection of angiomyolipoma after sirolimus pretreatment in patients with tuberous sclerosis". Patients treated with Sirolimus had a 38 to 95% reduction in AML volume [47].

The efficacy of selective renal artery embolization was demonstrated in a study conducted on 30 patients with large renal AMLs (mean size of 8 cm). In 83% of AMLs that were embolized, the procedure was complete after a single sesion. The median reduction volume was 43% at a follow-up of 6 months and 81% at 12 months. They found that the response was poor for fat-rich AMLs compared with fat-poor tumors [48].

De Luca stated that sporadic AMLs smaller than 1.5 cm showed no growth over 5 year follow-up in 92% of cases [49]. Furthermore, Oesterling et al said that AMLs greater than 4 cm in diameter grow more rapidly and other authors found that younger patients compared with older individuals had a higher risk of progression [50, 51]. On the other hand, epithelioid variants of AMLs have a poorer prognosis. In one study conducted on 40 patients with renal epithelioid AMLs and atypia detected on histologic examination, local recurrence or distant metastases were present in 26% of cases [52]. Nese et al had the same results in their study on 41 patients with pure epithelioid AML, out of which 36% had a metastatic disease at the time of presentation, and 16% developed metastatic disease during follow-up [53].

CONCLUSION

AMLs are a benign group of renal tumors, commonly associated with TSC and LAM, but can also appear sporadically in the population. The detection of AMLs is increasing because of an increase in the use of imaging and advances in imaging technology. The diagnosis of AML is generally made by imaging in asymptomatic patients, although a biopsy may be required to diagnose fat-poor lesions. In terms of therapeutical management, several treatment option are available, though a small percentage of patients require it and the treatment should be individualized for every patient. Most of the AMLs can be managed by active surveillance. Pure epithelioid variants of AMLs have a poor prognosis comapared with the clasic variant.

Renal involvement in primary retroperitoneal tumors

Dan Mischianu[1,2,3], Lucian Iorga[1], Dragos Marcu[1,2], Agnes Ciuca[2], Ioana Bratu[4], Raluca S. Costache[2,5]

Abstract: *Retroperitoneal tumors grow quietly and are generally large in size, more than half of them being larger than 20 cm at the time of diagnosis. They usually present several therapeutic challenges because of their rarity, relative late presentation and anatomical location, often in close relationship with several important structures in the retroperitoneal space. Due to intimate relationships with vital organs in retroperitoneum, extensive surgery with en bloc resection of the involved organ is often required, most frequently the kidneys, followed by colon, pancreas and spleen. Malignant tumors have a poor prognosis, the most significant factors regarding survival rates being delayed diagnosis, high histological grade, inoperability due to invasion into vital organs, and a positive surgical border.*

Keywords: *primary retroperitoneal tumors, renal involvement, therapeutic management*

INTRODUCTION

The retroperitoneum is one of the largest spaces in the body, located behind the abdominal cavity, between the posterior leaf of the parietal peritoneum and the lumbar muscles fascia. It is delimited superiorly by the diaphragm and extending inferiorly to the pelvic floor, reaching the external borders of the lumbar muscles laterally [1]. It contains connective tissue, kidneys, adrenals, ureter, aorta with its branches, inferior vena cava with its tributaries, a portion of the duoden and pancreas, a part of the descending and ascending colon and lymph nodes. At the kidneys level, the retroperitoneum is divided into three spaces by the anterior and posterior renal fascia, as follows: anterior pararenal space, perirenal space and posterior pararenal space [2]. Primary retroperitoneal tumors represent a rare, but interesting group of neoplasms. Even though they are located in the same space, tumors of the kidneys, adrenals and pancreas, tumors originating from the organs situated partially in the retroperitoneum and retroperitoneum metastasis do not fall into this category. Primary retroperitoneal tumors do not originate from any retroperitoneal organ (parenchymatous or not), but develop from the actual retroperitoneal tissue (lymphatic, nervous, vascular, support muscle, connective, or fibroareolar tissue) or from embryonic rests of the urogenital ridge (wolffian or müllerian ducts, germ cells, primitive notochord) [3-6].

The retroperitoneum can host a wide spectrum of pathologies. Primary retroperitoneal tumors are a rare entity, having a reported incidence of 0.3-3.0%. More than half of the retroperitoneal masses are malignant (70-85%), leaving a percentage of 15-25% of the tumors to be benign. The majority of the tumors are of mesenchymal origin (75%), followed by the neural origin (24%), and last from embryonic

rests (less than 1%) [7].

The retroperitoneum represents the second most common site of origin of malignant mesenchymal tumours after the lower extremities [7, 8]. Liposarcomas (70%) and leiomyosarcomas (15%) are the two most frequent histological subtypes of sarcomas. These tumors present as hard abdominal masses with an irregular surface; they are surrounded by a capsule that is rapidly outgrown by tumor growth and infiltrate the posterior parietal peritoneum and the intra-abdominal viscera attached to it, thus becoming intraperitoneal by direct, and not metastatic, invasion.

Benign tumors are often an incidental finding during an investigation for unrelated symptoms. The most common primary benign pathologies encountered in the retroperitoneum include benign neurogenic tumours (schwannomas, neurofibromas), paragongliomas (functional or non-functional), fibromatosis and retroperitoneal lipomas [9, 10].

Due to the inaccessibility of the region and since these tumours often give none or non-specific symptoms until they have reached a substantial size, they are usually large at presentation [11]. They grow silent and aggressively and usually invade the surrounding structures. In primary retroperitoneal tumors lymphadenopathy and distant metastases are a rare entity. More than half of the retroperitoneal tumors are larger than 20 cm in diameter at the time of diagnosis, the retroperitoneum space being “adaptable”.

The urologist has a crucial role in diagnosing and treating these tumors, because they are usually found in the anatomical region commonly used for surgical access in many major urological surgeries. However, in certain cases, a multidisciplinary approach should not be avoided.

Retroperitoneal tumors occurs frequently in the 5th and 6th decade, being found more often in female than in male patients [12, 13]. Certain histological types, such as embryonal rhabdomyosarcoma, teratoma and neuroblastoma, are commonly found in younger patients. Patients with primary retroperitoneal masses usually present with abdominal swelling and pain, early satiety, abdominal discomfort, most having a palpable abdominal mass. Many benign tumors are discovered as an incidental finding during imaging for unrelated symptoms [14, 15]. Pain can vary in intensity and severity and can also be located in the lumbar, inguinal or gluteal region. General symptoms such as asthenia, anorexia, weight loss or prolonged fever may be present. A study found out that out of the total number of patients, 44% had on admission gastro-intestinal symptoms such as: vomiting, abdo-minal distention, bloating, constipation, dyspepsia, gastrointestinal bleeding or intestinal blockage. Neurological symptoms (lower limb weakness, sensory loss of the obturator, femoral cutaneous or sciatic nerve, radiculitis, sciatica and sphincter dysfunctions) were also found in 3 out of the total 27 patients, and 10% showed signs of venous compression (edema, varicocele, ascites and genital swelling).

Retroperitoneal masses are usually diagnosed by clinical examination associated with blood tests and imaging studies (CT, MRI, abdominal ultrasonography). The imaging test of choice in the evaluation and staging of primary retroperitoneal masses is contrast-enhanced computed tomography of the thorax, abdominal and pelvic regions. It can distinguish between different densities which suggest the nature of the mass, defines the shape and size of the tumor, can discover enlarged lymph nodes and can assess the involvement of the neighboring organs [16, 17]. It can also be used to perform CT-guided biopsies. It can detect the presence or absence of pulmonary, bone, hepatic or peritoneal metastases and local or regional recurrence in patients who have already been treated [18].

It is important to confirm that the tumor is located within the retroperitoneal space and to exclude the possibility that the tumor originates from a retroperitoneal organ. Anterior displacement of the retroperitoneal organs is a strong indicator that the mass has a retroperitoneal origin. The migration of the large vessels can be helpful as well [19, 20].

Ultrasound is a fast, easy to use, repeatable method. It can reveal whether the mass is cystic or not, it can determine its volume, topography and can assess the condition of the inferior vena cava. The main disadvantage is that it is a subjective method, dependent on the doctor's experience [19].

If after the results of the imaging studies the diagnosis remains uncertain, an exploratory laparotomy or laparoscopy remains a last diagnostic resource.

THERAPEUTIC MANAGEMENT

Complete surgical resection is the treatment of choice for primary retroperitoneal tumors, but local recurrence occurs in the majority of the patients, being responsible for more than 75% of sarcoma-related deaths. Complete surgical ablation is not always possible, because of its invasion in vital structures. Despite the possibility of performing large organ resections, the possibility of a residual tumor is very high.

Macroscopic excision, tumour grade, multifocality and histological subtype are the main prognostic factors that dictate local recurrence and overall survival rates [21-23]. Local recurrence rates are higher and occurs at an earlier interval in high-grade tumors compared with low-grade ones. The possibility of obtaining negative margins is remarkably lower at the time of local recurrence and each successive operation is more difficult than the last. In the presence of a positive surgical border following the resection of a malignant retroperitoneal tumor, the 5-year survival rate decreases to 28%.

The most significant factors regarding survival rates are delayed diagnosis, high histological grade, inoperability due to invasion into vital organs, and a positive surgical border. For patients with high-grade tumors, the mean life expectancy is approximately 20 months, increasing to 80 months in patients with low-grade retroperitoneal masses.

A study found that tumors larger than 10 cm generally had distant metastasis at the time of diagnosis [24]. The risk of local recurrence is more important than the risk of metastasis regarding the progression of malignant primitive retroperitoneal tumors [25].

Due to the fact that a radical surgery is needed and that the tumor is usually large in size, an access route that allows a wide exposure for procedures is required. Midline laparotomy is the acces route of choice, allowing simultaneous examination of the abdominal and pelvic viscera, enabling management of the large vascular trunks, additional visceral surgery and the incision can be extended for access in the thoracic cavity. Chevron incision is usually used to remove large tumors with the invasion of inferior vena cava and lombotomy should be used to remove small retroperitoneal masses [26].

Because of the high risk of local recurrence, a strict follow-up with CT or MRI testing is necessary every six months for 2 or 3 years [27, 28]. Since primary retropritoneal tumors have such high rates of local recurrence, adjuvant therapy is recommended.

The use of high-dose therapy, in an attempt to lower the rate of local recurrence, is limited because these tumors are often adjacent to radiosensitive structures with low radiation tolerance (such as kidneys and intestines). The doze usually used is about 60 Gy, studies found that therate of local recurrence is 67% with doses below 50 Gy but only 17% at doses equal to or higher than 50 Gy [27]. Lymphomas, rhabdomyosarcomas, neuroblastomas and undifferentiated sarcomas seem to have good results with radiotherapy.

The use of chemotherapy in retroperitoneal tumors is controversial, having a similar response index with other therapeutic regimen and equally poor in single drug therapy or in combination [18]. The most commonly used drug, both in single drug therapy or in combination (adriamycin – dacarbazine, or cyclophosphamide – vincristine – adriamycin – dacarbazine), is Adriamycin. This drug is also used for metastatic disease, as a palliative form of treatment [28, 29].

If a tumor is considered unresectable or the patient has distant metastases, a core needle biopsy may be indicated to confirm the diagnosis and to enable consideration of alternative therapy.

Palliative surgery (incomplete resection for unresectable tumor) should be considered for symptom control and may improve quality of life [28].

DISCUSSION

Due to the fact that kidneys and ureteres are retroperitoneal organs, they are usually involved by retroperitoneal masses, either by extrinsec compression or direct invasion. If the tumor is left unchecked, it will grow to cause secondary hidronephrosis and renal parenchymal destruction that will lead to chronic kidney disease with severe hydro-electrolytic imbalance and serious consequences. Resistant hypertension [30] with dyselectrolytemia [31, 32], secondary heart failure [33] and cardiac arrhythmias [34] may be the result of compromised renal arteries by extrinsec compression caused by the retroperitoneal masses [9].

Urological manifestations, caused by possible urinary tract involvement (displacement, compression and invasion) at any level (kidneys, ureter, and bladder) were not as frequent, only 25% of the patients presented chronic lower back pain, or acute renal and ureteral colic. Hematuria, polakiuria, dysuria or urinary retention usually occur in tumors located in the pelvic region, near the bladder [13]. Hematuria may also appear if the retroperitoneal mass invades the ureters or the pyelocaliceal system [35].

In terms of treatment, the complete surgical resection of the tumor en bloc with the involved organs is the gold standard. It can vary from segmental ureterectomy, followed by a surgical repair of the defect, to radical nephrectomy. In cases with extrinsec compression of the ureter and secondary hidronephrosis, with no signs of invasion, an internal (ureteral stent) or external (percutaneous nephrostomy) renal drainage method can be used, until the tumor can be surgically removed. More than 83% of the patients require resection of neighboring organs, most frequently the kidneys, followed by colon, pancreas and spleen, for achieving a negative margin [27].

If the ureteral defect after extensive surgical removal of the retroperitoneal mass is proximal to the ureterovesical junction and it is not large in size, a ureteroneocystostomy or a primary anastomosis of the ureter (ureteroureterostomy) is usually preferred. When ureteroureterostomy or ureteroneocystostomy cannot be performed, the psoas hitch ureteral reimplantation is the best approach. For defects in the middle third of the ureter after partial ureterectomy, the optimal approach is ureteroureterostomy, but if it cannot provide a tension free anastomosis, a Boari flap is an optimal, but complex approach. The optimal procedure for repair of an upper ureteral injury is a ureteroureterostomy, if it can be performed without tension. A nephropexy with fixation to the psoas tendon can provide a tension-free anastomosis. When a tension-free anastomosis cannot be achieved, even after kidney mobilization, autotransplantation, ileal or appendiceal interposition graft, nephrostomy or a cutaneous ureterostomy can be performed. The ureteral anastomosis following any type of primary repair is typically stented.

In advanced cases, with inoperable tumor and secondary ureterohydronephrosis, an urgent drainage of the obstructed kidney should be used [36]. This can be achieved either by internal drainage using a double J ureteral stent [17] or by using a percutaneous nephrostomy. A nephrostomy deteriorates the patient's quality of life and leads to frequent infections, blockage of tubes or bleeding. Ureteral stenting, on the other hand, can be associated with irritative bladder symptoms, blockage, sepsis and a high failure rate, which ultimately leads to a nephrostomy tube [28].

Wrona AJ et al wanted to offer a better solution than ureteral stenting and nephrostomy for kidney drainage. In their study, they presented a subcutaneous pyelovesical bypass as a solution for ureteric obstruction (detour bypass). A detour bypass is made of two coaxial tubes, a 27F porous polytetrafluoro-ethylene (PTFE) outer tubeand an inner 17F silicone tube extending beyond the PTFE, with perforations on both ends and a radio-opaque ring on the proximal end (for an accurate placement of the proximal end of the stent). The detour is placed subcutaneously, using a tunneling device, and the distal end of the tube is placed into the dome of the bladder by a small incison. They concluded that this method is a safe, minimally invasive and highly effective alternative in patients with ureteral obstruction caused by both malignant and benign diseases and that the potential complications (infection, encrustation) may be easily and efficiently managed [37].

Andrea Montenegro et al presented a case of a 65 year-old female with a large retroperitoneal liposarcoma, in whom, due to the fact that it was very adherent to the left kidney, a complete resection of the tumor with concomitant left nephrectomy was practiced.

In a case report by Mariko Tanaka et al, they introduced the case of a 60 year old female who presented with abdominal distension. The CT revealed a large retroperitoneal tumor which proved to be a dedifferentiated liposarcoma at biopsy. Due to the fact that the tumor invaded the duodenum, head of the pancreas, right kidney, inferior vena cava and the aorta below the left renal artery, an extensive surgical removal of the tumor was performed, with en bloc resection of the right kidney, duodenum, head of the pancreas, a portion of the inferior vena cava and abdominal aorta, with concomitant vascular reconstruction [38].

In their study, Rodriguez et al found out that sarcomas, mainly liposarcomas, followed closely by leiomyosarcomas, were the most common type of primary retroperitoneal tumors. More than half of the patients included in the study presented at admission pain of varying severity and location (mainly abdominal and lumbar) and general symptoms such as asthenia, anorexia, weight loss or prolonged fever. Gastrointestinal manifestations (vomiting, abdominal distention, bloating, constipation, dyspepsia or intestinal blockage), due to compression/invasion of the gastrointestinal tract, were present in 44% of cases. Renal involvement was not as frequent, only one quarter of patients had urological symptoms, such as lower back pain, but also dysuria, polakiuria and urge [13].

Pereira et al reported the case of a 48-year-old male who presented for pain and right abdominal swelling. Clinical investigation revealed a right varicocele and imaging studies found a solitary hydronephrotic right kidney (personal history of left renal agenesis). Contrast enhanced computed tomography showed a retroperitoneal mass and a right hydronephrotic kidney. The particularity of this case was the presence of a solitary right kidney with left renal agenesis, with the possibility that the patient will become anephric after extensive surgery. Ultrasonography-guided biopsy was performed that confirmed a well-differentiated liposarcoma. Surgical excision of the retroperitoneal sarcoma was performed, sparring the right kidney, but the patient unfortunately died during chemotherapy [39-42].

Another case reported by the previous team presented with hypertension, anorexia, and weight loss (10 kg in 2 months). This patient had a solitary right kidney following a left radical nephrectomy subsequent to renal cell carcinoma. A right retroperitoneal mass was found during the study of his hypertension, which had a compressing effect on the right renal artery. Surgical excision of the mass was performed, but the patient died of local recurrence.

MRI of an 84-year-old male, who presented with complaints of pain and a palpable right lumbar mass, revealed a large retroperitoneal tumor invading the right kidney. Extensive surgical excision was made, with concomitant right nephrectomy.

Kazim et al stated that the location of intra-abdominal organs can shift in the presence of retroperitoneal tumors, due to the mass effect, with the kidneys being the most common viscera with an altered intra-abdominal location. In their series, they reported one retroperitoneal tumor, measuring 30 cm in diameter that pushed the left kidney to the right anterolateral direction. Since the left kidney was completely engulfed by the mass, the patient underwent extensive surgical excision of the mass and a left nephrectomy [43].

CONCLUSIONS

The retroperitoneum can host a wide variety of pathologies, including benign and malignant tumors. Primary retroperitoneal tumors are rare, almost all of them being malignant. Retroperitoneal masses grow silently, presenting late, usually invading neighboring structures at time of diagnosis. Contrast-enhanced computed tomography is the best way to evaluate this kind of tumors. Complete surgical resection is the only potential curative treatment modality for retroperitoneal masses, but the characteristics of retroperitoneal tumors (size, proximity to abdominal organs and structures, proximity to large retroperitoneal vessels) make surgical treatment a real challenge for surgeons. The efficiency of pre-operative and post-operative radiotherapy and chemotherapy is still a controversial issue, complete surgical excision with negative margins remains the gold standard procedure.

Research for the development of logistics planning information support in health protection against biological agents

Lucia E. Ionescu[1], Viorel Ordeanu[1,2], Manuel Dogaru[3], Marius Necșulescu[1], Diana M. Popescu[1], Simona N. Bicheru[1], Gabriela V. Dumitrescu[1]

Abstract: *Making medical countermeasures requires documentation to assess vulnerabilities, threats and operational risks and bioterrorism through the collection and processing of specific multidisciplinary data in human medicine, veterinary, phytosanitary, the environment, defense and national security, etc. Based on retrospective data and late information (medical intelligence), we can estimate the prospective risk to public health, respectively for troops and civilian population in a given area, the area of operations.*

The biological military or bioterrorist attack, whether overtly or masqueraded as human or animal epidemics can cause a major biological crisis for troops and the civilian population, for domestic and wild animals, for crops or wild plants or for the environment, which remains contaminated.

Therefore, it is important to constantly monitor the situation of infectious diseases in the area of responsibility (national territory, operations theaters) to assess vulnerability, threat and bioterrorist risk but also for making medical anti-bioterrorist countermeasures, which can only be effective by genuine cooperation between all specialized structures of the Ministry of Defense, other departments and the civil society.

Keywords: *biological attack, bioterrorism, medical countermeasures, logistics support, medical treatment*

INTRODUCTION

Medical protection logistics planning against biological warfare agents (ABR) is based on interdisciplinary studies and specific calculations.

The complexity of this approach involves processing a database of medical, pharmaceutical and logistics that can only be operated in real time by using a suitable IT support. It consists in hardware (IBM compatible standard configuration computer), software (Windows based NATO specific program), specialized personnel (NATO computer operators, specialists in military medicine, logistics, CBRN defense, etc.) and properly equipped and secure space.

Scenarios that simulate hypothetical situations reported in the territory, will be tested by constructive simulation as functional experimental models of "war games ".[1]

EXPERIMENTAL MODELS

Making the experimental model of the information system for constructive simulation for medical protection against biological weapons and bio-terrorism and testing it as a military medical exercise demonstrated and validated the scientific data, using modeling and constructive simulation, together with UNAp/CISM, the current Center for War Games and doctrinal Experiments (CJRED) of the General Staff. [2] It was awarded a large database that can be exploited in different complementary approaches. Of all bacteria, Bacillus anthracis has been chosen for being used in the constructive simulation experiment, it is known as the biologically bacterial agent most used for biological attacks. [3]

Medical countermeasures must be known and individualized for each situation and appropriately applied, with appropriate forces and means. This requires an adequate and efficient logistic support because the scale of medical needs (medicines, sanitary materials, reagents, accommodation, transport, etc.) exponentially increases during an epidemic. As a result, at any level, health-pharmaceutical materials are rapidly becoming inadequate. The unintended consequence is that we cannot prevent illnesses or treat patients, so the affected communities are no longer capable of fighting and working and there is a risk of over mortality. Therefore, the medical protection against biological weapons requires a proper logistic planning that is also based on statistical analysis of some relevant information for this purpose. The exploitation of such data requires a dedicated computer system, with suitable software, trained personnel, quick and secure media and communications, etc. Because the computer system for the surveillance of infectious diseases caused by combat biological agents and by bioterrorism to be reliable, it must be implemented in stages, with feedback in the form of custom scenarios for biological attack or epidemic outbreak.

Achieving this pilot experiment in the Romanian Army, demonstrated the usefulness of extending simulation tests on other categories of warfare and on specific logistics for biological crisis. The system used was JCATS – Joint Conflict and Tactical Simulation. The information was delivered in the form of screen-shots that required image processing, computer analysis and interpretation. [5]

The data was processed and a computer media has been made for logistics planning of medical protection against biological warfare and bioterrorism agents through statistical analysis of the resulting data bank. To estimate the number of contaminants analysis were carried out on the three simulated hypothesis: without sensors, with military sensors and alarm on short (in barracks) and with military sensors and alarm on short distance (in barracks) together with a sensors system of the local Inspectorate for Emergency Situations (ISU) and alarm in the city. We have obtained information that was collated for each simulation, in numerical tables and graphs illustrating the impact such an undesirable event can have. [6]

The obtained data allowed the dynamic evaluation (an estimate every 5 minutes) on the effects of a biological attack with anthrax on cities with different number of inhabitants and military forces.

The post exercise analysis showed that in terms of exposed population, where a relatively small number of people, the presence of the sensor is useful, the number of people being affected (civilian and military) decreased after they triggered the alarm.

In a similar situation, in the case of larger cities it has been observed that activation of military sensors does not cause diminishing the number of affected civilians, but decreases the number of infected soldiers.

The comparative analysis of the post-biological attack, for the soldiers of the sea shows that there are a huge number of people affected in the absence of any alarm sensor (over 50%) as their protection or travel ability is restricted to the soldiers on land. Also, the percentage of affected soldiers who do not benefit from the ship protection is higher (70%), if they go out on the deck.

The major differences recorded between the high percentage of affected civilians and that of the military, leading to the idea that it is useful and necessary for the civilian population to be at least more informed about how they should act when triggering an alarm of any kind. [7]

Following statistical analysis of the database resulting from constructive simulation system experimentation resulted in an acquisition, storage, retrieval and information-processing algorithm as an interactive database. [8]

SANITARY LOGISTICS

The statistical analysis conduct to information somehow surprising by the extremely high number of people affected, at least from the civilian population, which is not trained to respond to any alarm. Regarding the military, which is a segment of the relatively "trained" population compared to civilians, we found that the number of those affected drastically decreases, especially when special sensors for detection exist. The analysis of relevant simulation for the purpose of the experiment showed that a possible attack with anthrax spores, even if it is not repeatable, it could result in a significant number of contaminated, many of which will develop the disease, and some will die. The evolution of the epidemic will depend on the capacity of the health system (military and civilian) to promptly and adequately act with the necessary forces and means and with the appropriate logistic support, depending on the epidemiological situation of the troops and the civilian population. [8]

This means that all exposed persons should be medically supervised: rapid laboratory analyzes for different areas/neighborhoods, nasal/throat exuding for identifying B. anthracis.

The contaminated must be prophylactic treated, also with antibiotics according to the therapeutic scheme Guide for 60 days and under medical supervision. Patients should be isolated and treated for 60 days. For those with severe forms (pulmonary anthrax) intensive oxygen therapy must be also applied, etc. [9, 10, 11]

The deceased must be disinfected and handed over to and Funeral Services (the civilians) or the Logistics department (military) for transport and burial, in accordance with epidemic provisions. Incineration is contraindicated due to the large number of corpses. Repatriation is not allowed because of the contagion risk. [12]

Overall, the medical forces and means are overburdened and there is an urgent need for specific additional procurement for a 7 week period.

For such need, specific measures are necessary because sanitary-pharmaceutical materials are rapidly becoming inadequate and the only way to overcome the situation involves cooperation with all own and allied military forces as well as civil-military cooperation (CIMIC).

CONCLUSION

- Medical countermeasures against biological or bioterrorist attack are complex and require specialized forces and means, in very large quantities and in real time.
- By medical intelligence the real situation must be known and the short, medium and long term development must be assessed in order to correctly estimate the forces and means necessary for the medical countermeasures.
- By appropriate application of the logistics assurance principles and CIMIC cooperation the specific logistical support can be achieved, necessary to carry out the medical countermeasures for the prevention of diseases and treating patients.
- The logistical support for medical countermeasures against biological or bioterrorist attack must be coherent, efficient and fast.

Abstract: *Chemotherapy is an important treatment in oncological disease, with a vast number of side effects. The cardiotoxicity of several chemotherapeutic agents and appropriate risk stratification and patient follow-up must be ensured by a multidisciplinary team which must include an oncologist and a cardiologist. Lynch syndrome is associated with younger-onset malignant tumors of various localizations, requiring aggressive chemotherapy. FOLFOX chemotherapy which is frequently used in Lynch syndrome-associated colorectal cancer has several cardiotoxic effects with mechanisms ranging from increased reactive oxidative species to Krebs cycle blockade or coronary vasospasm. These complex effects on the cardiovascular system have varied clinical effects, such as heart failure, arrhythmias, or acute ischemic events***.**

Keywords: *heart failure, bradycardia, cardiotoxicity, chemotherapy, Lynch syndrome, FOLFOX, colon cancer, cardio-oncology*

INTRODUCTION

Cancer therapy is life-saving for patients requiring such medication. However, a wide array of side effects have been described, depending on the treatment used and the history and risk factors of the patient. Cardiotoxicity has been described as a side effect of many chemotherapic drugs.

In young patients with oncological disease, the diagnosis is usually determined at a later stage, requiring more aggressive chemotherapy. Moreover, younger-onset cancers might be associated with hereditary diseases, such as Lynch syndrome. This syndrome is associated with early-onset cancers of varied localizations, from colorectal cancer to endometrial cancer.

We present Lynch syndrome chemotherapy cardiovascular side-effects for the most commonly associated cancers.

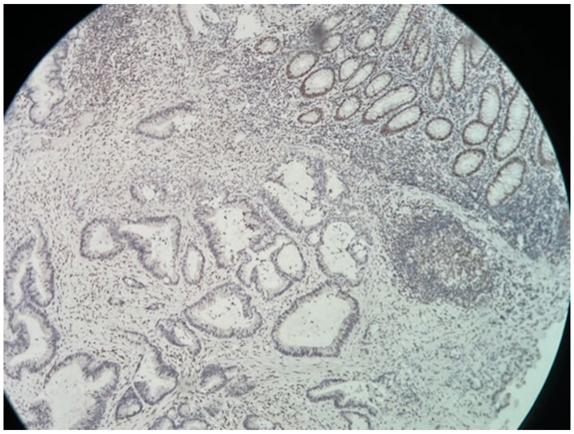
DISCUSSION

Cancer is no longer a pathology reserved for the elderly. Several studies reveal an alarming increase in the incidence of colorectal cancers for young patients. Colorectal cancers at a younger age are more often localized on the left colon, are less differentiated, more advanced at diagnosis, and have a higher prevalence of signet cells. 30% of early-onset patients have hereditary cancer-predisposing syndrome mutations and 20% have familial colorectal cancer [1,2]. In clinical practice, still, in a young patient, cancer is often a diagnostic of exclusion, rarely taken into consideration due to its low incidence and nonspecific signs and symptoms. There are several distinct characteristics of cancer in the young population. These people often have no other diseases requiring frequent medical visits which might lead to a delayed diagnosis, with no potential surgical treatment. Moreover, the chemotherapy regimen used in advanced cancers is more aggressive, both in dosage and in the agents required, leading to various potential side effects and drug interactions that have to be managed by the medical team. The cardiotoxicity of these compounds is variable and has to be taken into consideration and monitored accordingly [3].

To assess the cardiac toxicity of various chemotherapy agents, several tests can be used – ECG, biomarkers (troponin, natriuretic peptides), and imaging. Cardiac echography is the most used imagistic test. Advanced echocardiographic methods using myocardial deformation analysis are important, as they can detect early alterations of cardiac function. Using Color Doppler tissue imaging, strain, and strain rate data can be collected and plotted to assess global and regional cardiac systolic function. Diastolic strain and strain rate data can be obtained, but it is not widely used. Global longitudinal strain reduction has been used as a parameter of global cardiotoxicity because it is modified earlier than LVEF in patients undergoing chemotherapy. However, there is significant inter-vendor variability in GLS cut-offs. Moreover, some agents such as anthracyclines may cause peak strain rate reduction even before inducing diastolic dysfunction, which suggests that some chemotherapic agents may cause initial systolic dysfunction without diastolic dysfunction [4].

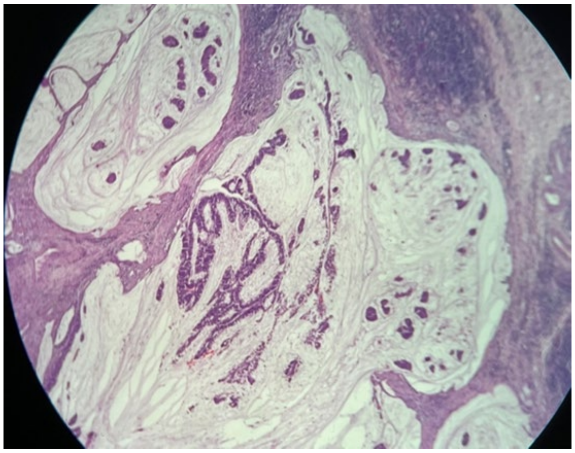
An important cause of cancer in young patients with no other comorbidities is Lynch syndrome, which is the most common cause of inherited colorectal cancer (hereditary nonpolyposis colorectal cancer). It is an autosomal dominant disorder caused by mutations in various DNA mismatch repair genes, such as MLH1 (3p22.2), MSH2 (2p21-16), MSH6 (2p16.3), PMS2 (7p22.1), leading to early carcinogenesis. Mutations in the MSH2 gene are the most frequent, followed by MLH1 mutations [5], [6]. Loss of MLH1 expression is exemplified in Figure 1.

Figure 1: Loss of MLH1 expression in the tumoral cell mass



There are several cancers associated with Lynch syndrome, such as colorectal, endometrial, gastric, ovarian, renal/ ureteral, prostatic or skin cancers. The incidence of each type of cancer varies with the mutation involved in the etiology of Lynch syndrome. The classical aspect of Lynch syndrome associated with colon cancer can be seen in Figure 2. The prognostic of the affected individuals and the personalized screening program varies according to several variables. These variables include the pathogenic variant involved, the personal and familial history of cancer, and age at the first oncologic diagnostic. The most frequent malignancy is colon cancer, which is most frequently right-sided and can be associated with synchronous or metachronous tumors of different localization. Furthermore, the adenoma-carcinoma sequence in Lynch syndrome is accelerated and the cancer can develop directly from mucosal crypts in the colon [7].

Figure 2: HE, 10X, Mucinous colon adenocarcinoma with lymphocytic infiltration



For about 50% of females that carry one of the LS mutations, the first malignant lesion is an endometrial carcinoma. Women with Lynch syndrome have a lifetime cumulative risk is 40-60%. This risk is similar to or exceeds their risk of colorectal cancer [8].

In young individuals with malignant tumors, genetic testing of the patient and their family members is paramount. All patients with colorectal cancer must be evaluated for DNA mismatch repair gene deficits by immunohistochemistry or microsatellite instability (MSI) by PCR [9]. Revised Bethesda Guidelines can be used to assess the need for oncogenetic screening.

According to the aforementioned guidelines, oncogenetic screening should be performed to [10]:

1. Patients with a diagnosed colorectal cancer before 50 years of age;

2. Patients with synchronous or metachronous colorectal tumors or with any other HNPCC-associated tumors, regardless of the patient's age;

3. Patients with colorectal cancer with MSI-H histology before 60 years of age;

4. Patients with colorectal cancer diagnosed in one or more first-degree relatives with an HNPCC-related tumor, with one cancer being diagnosed before 50 years of age;

5. Patients with colorectal cancer are diagnosed in at least two first or second-degree relatives with HNPCC-related tumors,

regardless of age.

Amsterdam criteria have been modified since their original proposal, however the 3-2-1 rule remains useful in clinical practice, due to its' simple applicability: at least three relatives should have histologically confirmed CRC, spanning at least two successive generations and with at least one colorectal cancer being diagnosed before 50 years of age [11]. However, in current practice, the guidelines recommend the use of the Revised Amsterdam criteria. These criteria diagnose Lynch syndrome in patients with at least three relatives with HNPCC-associated cancer (colorectal cancer, endometrial cancer, enteral cancer, ureteral cancer, or renal pelvis cancer) associated with [12]:

1. One relative should be a first-degree relative to the other two;

2. At least two successive generations should be affected;

3. At least one patient should be diagnosed before 50 years of age;

4. Familial adenomatous polyposis should be excluded;

5. Tumors should be confirmed by pathological examination.

Cardiotoxicity of chemotherapy agents has been classified into type 1 and type 2 agents. Class 1 agents have dose-related cardiotoxic effects, that are mostly irreversible. They are cytotoxic and cause necrosis and apoptosis of cardiac cells, increasing troponin levels. Class 1 agents have a variable incidence of LV dysfunction, its' incidence increasing in the following order: antimicrotubule agents (docetaxel/paclitaxel) <alkylating agents (cyclophosphamide, 5-FU) <anthracyclines (doxorubicin, idarubicin, etc.). Cyclo-fosfamide may cause hypertension, myocardial infarction, Raynaud phenomenon, or hepatic vein occlusion [13]. Class 2 agents have variable cardiotoxicity even in the same category. Class 2 agents have a more complex pathophysiology, but their effects are generally reversible. In this class, anti-HER2 agents, VEGF inhibitors, and TK inhibitors are to be mentioned. They cause cellular dysfunction, leading to transient LV dysfunction [14–18].

One of the most important chemotherapy regimens in colon cancer is the FOLFOX regimen, which includes 5-fluorouracil, Folinic acid, and Oxaliplatin. The addition of oxaliplatin reduces relapse in stage III colorectal cancer compared to a regimen of 5-Fluorouracil and folinic acid [19]. To prevent cardiotoxicity development in cancer patients, the new guidelines for Cardio-oncology recommend risk stratification tools, such as the HFA-ICOS risk stratification [20]. In our presented case, VEGFi therapy cardiotoxic risk stratification could be guided by this score. Risk factors and their stratification in VEGFi therapy are exemplified in Table 1.

Table 1: Risk stratification for VEGFi

M1 risk factors	M2 risk factors	H risk factors	VH risk factors
Elevated baseline cTn or NP	Arrhythmia	DVT/PE	HF/Cardiomyopathy/CTRCD
Radiotherapy to left chest/mediastinum	$450 \le QTc < 480$ ms (men) $460 \le QTc < 480$ ms (women)	$QTc \ge 480$ ms	MI/PCI/CABG/Stable angina
Age 65-74	LVEF 50-54%	LVEF < 50%	Arterial vascular disease
CKD, Proteinuria, DM or hyperlipidemia		Age > 75 years	
Smoker/smoking history Obesity (BMI>30 kg/m^2)		HTN	

cTn, cardiac troponin; NP, natriuretic peptides; CKD, chronic kidney disease; DM, diabetes mellitus, BMI, body mass index, QTc, corrected QT; LVEF, left ventricle ejection fraction; DVT, deep venous thrombosis; PE, pulmonary embolism; HTN, arterial hypertension; HF, heart failure; CTRCD, cancer therapy-related cardiac dysfunction; MI, myocardial infarction; PCI, percutaneous intervention; CABG, coronary artery bypass graft;
Risk level: low risk (no risk factors or one M1 risk factor), moderate risk (moderate risk factors with a total of 2-4 points; M1 = 1 point, M2 = 2 points), high risk (moderate risk factors with a total of at least 5 points or any high-risk factor), very-high risk (any very high-risk factor)

Fluoropyrimidines are a class of chemotherapy drugs frequently used in digestive neoplasia and breast cancer. This class includes drugs such as 5-Fluorouracil (administered IV), its' metabolic precursor capecitabine (administered po), and others, such as Tegafur, or TAS-102. They act by inhibiting thymidylate synthase, blocking the synthesis of nucleic acids, and causing the insertion of 5-FU metabolites in cells' nucleic acid. Not only do these effects occur in cancer cells, but also in normal cells of various localizations, causing cellular dysfunction in many tissues [21]. The most frequent cause of fluoropyrimidine toxicity is caused by a deficiency of dihydropyrimidine dehydrogenase, an important enzyme in the metabolism of fluorouracil, which is the first-rate limiting step in its catabolic pathway. The deficiency of this enzyme's activity leads to the accumulation of fluoropyrimidine in the body, increasing the risk of dose-related chemotoxicity. This enzyme is encoded by the DPYD gene, which has important interindividual variability [22]. In clinical practice, dose adjustment must be taken into consideration by testing for DPYD polymorphisms or by testing the patient's pharmacokinetics of the drug.

Moreover, the duration of 5-FU infusion is also important to prevent toxic accumulation of 5-FU. Elastomeric chemotherapy pumps are very important to ensure a slow release of the chemotherapic agent, with an infusion duration of 46 hours. The medical engineering of newer, more accurate elastomeric pumps may lead to a lower incidence of over- or under-dosing. Furthermore, different methods can be implemented to detect and reduce pump dysfunction, such as pump weighing by the patient [23]. Differences between 5-FU and capecitabine-related cardiotoxicity have been reported, with studies reporting a higher incidence of cardiotoxicity in the capecitabine group [24]. However, whereas exposure to capecitabine was more often associated with chronic heart failure compared to 5-FU, exposure to the latter was associated with cardiovascular diseases [25]. However, in the literature, there have been cases of severe reversible LVEF reduction described, from 65% to 15%, after the first dose of 5-FU containing chemotherapy [26].

Mechanisms of 5-FU-related cardiotoxicity have not been completely determined. Various mechanisms have been suggested, such as coronary vasospasm, direct myocardial injury, vascular endothelium dysfunction with associated thrombosis, or a-fluoro-b-alanine accumulation which causes a Krebs cycle blockade due to fluorocitrate accumulation [27–30]. Focal coronary vasospasm was documented in the early 1990s by Luwaert and co after 2 boluses of 5-FU. Moreover, in both animal and human models, endo-thelium-independent vasoconstriction has been associated with the administration of progressively higher doses of 5-FU [31]. Moreover, fluoropyrimidine-induced diffuse coronary spasm is caused by endothelial cytotoxicity. This has been demonstrated by cell edema, cytolysis, and vessel wall and cell contraction, associated with platelet adhesion, aggregation, and fibrin formation. A proposed mechanism is via endothelial nitric oxide synthase (eNOS), which is an important factor of vascular tonus. Furthermore, patients with 5-FU cardiotoxicity have increased levels of free radicals and endothelin-1, which is an important vasoconstrictor [32,33]. Dihydropyrimidine dehydrogenase, an enzyme involved in the 5-FU catabolism, also plays an important role in the myocardial impairment associated with fluoropyrimidine therapy [34].

3 platinum-based drugs are frequently used in the treatment of cancer: cisplatin, carboplatin, and oxaliplatin. Platinum-based drugs cause crosslinking of DNA, inhibiting nucleic acid replication and transcription. Moreover, it inhibits DNA repair and synthesis, leading to cell apoptosis. There are various side effects reported for this class of drugs, such as nephrotoxicity (AKI, renal tubular acidosis, hyperuricemia, hypomagnesemia), ototoxicity, neurotoxicity (peripheral sensory neuropathy), and cardiotoxicity. Various cardiological side effects of platinum-based drugs have been reported in the last decade, such as arrhythmias (ranging from sinus bradycardia to tachyarrhythmias or complete heart block), vasospasm (which might result in angina, acute coronary syndrome, or stroke), heart failure or thromboembolic events, hypertension, thrombosis (including cerebrovascular events). More data suggests that vascular toxicity is very important in platinum-based chemotherapy. Persisting circulating platinum causes endothelial dysfunction, increasing endothelial injury markers such as von Willebrand factor, tissue-type plasminogen activator, and plasminogen activator inhibitor-1. Moreover, an increased carotid-intima index has been reported [35–40].

Folinic acid (leucovorin) is added to 5-FU because it potentiates the effects of the latter [41]. Being used as an enhancer for 5-FU, the cardiotoxic effects of folinic acid alone have not yet been described.

Vascular endothelial growth factor signaling pathways are involved in both normal and pathological angiogenesis and ensure appropriate vascular permeability. VEGF binds to tyrosine kinase receptors, having different effects in different cells depending on the type of VEGF receptor [42]. Vascular endothelial growth factor inhibitors such as bevacizumab are used in the treatment of numerous cancer types with various localizations, ranging from colon to thyroid. However, VEGF inhibitors are associated with cardiovascular morbidity. The most frequently reported cardiovascular side effect is arterial hypertension, which is dose-dependent and reversible upon drug discontinuation. The mechanism is related to the effect of anti-VEGF drugs on cancer cells, by inhibiting VEGFR2, leading to reduced NO production in vessels, increasing ROS, and determining vasoconstriction [43]. Several mechanisms involved in VEGF inhibitors-induced hypertension were also described: vascular remodeling along with a decrease in microcapillary density (vascular rarefaction) that subsequently leads to an increased systemic vascular resistance, increased endothelin-1 levels, or autonomic nervous system toxicity [44].

Other side effects are heart failure, acute vascular events (arterial events such as aortic dissection, stroke, vasospasm, arterial and venous thrombosis, and thromboembolism), and significant QTc prolongation [42,45–49].

Even if VEGFi associated FOLFOX regimen has been efficient in HNPCC-associated colorectal cancer, this is not a specific treatment. Lynch syndrome is associated with microsatellite instability and deficient mismatch repair, and specific immunotherapy with immune checkpoint blockers is highly efficient. Molecules such as Pembrolizumab (anti-PD-1 antibody, FDA approved in 2017) and Nivolumab [50] are available in the US and might come into current practice and national guidelines in Romania in the following years. In animal studies, PD-1 deletion causes autoimmune myocarditis in murine models, which was confirmed in some human trials. Anti-PD-1 treatments promote myocardial infiltration with both CD4+ and CD8+ T cells, with an increased activation level of the latter (which are also called cytotoxic lymphocytes). This increases the risk of autoimmune reactions in the myocardium and a dysregulated cellular metabolism, with proteomal alteration [51]. More PD-1 inhibitor-associated cardiovascular side effects are arrhythmias, cardiomyopathy (such as dilatative cardiomyopathy or Tako-Tsubo syndrome), pericarditis, or myocardial/cerebral ischemia. The proarrhythmic mechanism is considered to be autoimmune when myocarditis causes intracardiac conduction system alterations. This can lead to atrioventricular blocks. Another proarrhythmic mechanism is indirect. Immune checkpoint inhibitors can cause autoimmune thyroiditis which is associated with atrial fibrillation. The monitoring of cardiac side effects is very important, as CV events have a significant mortality. Tropoponin is a sensitive test for ICI-associated myocarditis, however non-specific, particularly in late-presentation patients [52,53]. Higher cardiovascular toxicity has been reported in dual ICI-therapy-treated patients (ipilimumab and nivolumab) [54–57]. Another important side effect that has been documented in immune checkpoint inhibitor anticancer therapy has been vasculitis, the most frequent one being temporal arteritis [58].

Endometrial cancer is also a frequent Lynch syndrome-associated neoplasia, with an incidence similar to CRC in women with Lynch syndrome. The chemotherapy regimens required to treat these malignancies are extremely potent, however, the patients develop significant side effects. The classes used are more varied than in CRC. Alongside already discussed alkylating agents, VEGFi, and platinum salts, we mention:

- Anthracyclines (such as Doxorubicin);

- Immune checkpoint inhibitors (Pembrolizumab, Dostarlimab);

- Taxanes (Paclitaxel, Docetaxel);

- HER2-inhibitors (Trastuzumab);

- TKI (Pazopanib, Lenvatinib).

These classes are not used at the same time, however, the arsenal of agents that can be used is more vast and the cardiovascular side effects must be taken into consideration. NCCN guidelines recommend cisplatin + radiotherapy + carboplatin/paclitaxel in chemoradiation therapy and carboplatin + paclitaxel + another agent (pembrolizumab or dostarlimab or trastuzumab depending on the stage of the tumor or its' HER-2 status).

Anthracyclines are frequently associated with left ventricular dysfunction and act by altering topoisomerase enzymes. These enzymes are responsible for DNA unwinding to allow nucleic acid replication. When topoisomerases are inhibited, tissue growth is impaired, causing oxidative stress pathways to become more active (such as MAPKs or SAPKs), which are important in cell survival, leading to programmed cell death in many tissues, such as the myocardium. [59] There are several other mechanisms proposed for anthracycline cardiotoxicity, such as impaired mitochondrial function, calcium homeostasis dysfunction, and autophagy. Moreover, it downregulates DNA-methyltransferase 1 (DNMT1), leading to hypomethylation and mitochondrial gene dysfunction (peroxisome proliferator-activated receptor γ coactivator-1-α/PGC-1a, nuclear respiratory factor 1/NRF-1, mitochondrial transcription factor A/TFAM). In cardiac cells, oxidative stress associated with doxorubicin damages the CKMB isoenzyme, generating peroxynitrite free radicals. Furthermore, cardiomyocyte apoptosis is stimulated by increasing heat shock factor 1 (HSF-1) which induces heat shock protein 25 (HSP-25). HSP-25 induction stabilizes the p53 protein, generating proapoptotic factors such as FasL, Fas, and c-Myc [60,61].

Taxanes can cause edema, bradyarrhythmias, or hypotension. They frequently potentiate anthracycline toxicity by increasing plasma levels of the latter, but may directly cause cellular lesions in cardiac cells by microtubule alterations, leading to an ineffective cytoskeleton required for cell regulation and proliferation [62]. In animal models, Paclitaxel increased TNF-α and Jun N-terminal kinase JNK expression, leading to cardiomyocyte apoptosis [63].

HER-2 inhibitor Trastuzumab (which is the prototype of class 2 chemotherapy drugs regarding cardiovascular toxicity) is associated with left ventricular dysfunction or heart failure. This is very important in anthracycline-treated patients, as they cause increased expression of HER2-HER4 survival pathways which are targeted by Trastuzumab, leading to cardiac dysfunction by ineffective HER2-HER4 pathways [64]. One suggested mechanism that has been observed in animal models is ferroptosis, which is a form of iron-induced cell death. Herceptin causes increased cellular in mitochondrial ROS and altered protein expression of glutathione peroxidase and recombinant solute carrier family 7 member 11 (SLC7A11) which were reversed by ferroptosis inhibitor ferrostatin-1 [65]. Another observed mechanism of HER cardiotoxicity has been by trastuzumab phosphorylation of HER1 and HER2 which triggers the autophagy-associated inhibitory Erk pathway in human cardiomyocytes, leading to cellular toxins accumulation in these cells [66]. However, the most likely mechanism of Herceptin cardiotoxicity is binding to an extracellular domain of HER2, inhibiting HER2-ErbB4 dimerization, which downregulates HER2 expression and triggers signaling of the PI3K-AKT-mTOR pathway. This pathway is involved in cell growth and proliferation. Furthermore, in anthracycline-exposed patients, myocardial cells are already undergoing apoptotic or necrotic cellular modifications, being more susceptible to trastuzumab cardiotoxicity and myocardiocyte death during HER-2 inhibitor treatment [67,68].

TKI has a wide range of side effects, ranging from hypertension or ischemia to QT prolongation, arrhythmias, or thromboembolism (venous or arterial) [69]. These effects can be explained by the complex intracellular mechanisms that can be altered in tyrosine kinase inhibitor treatment. One of these mechanisms is the increased endoplasmic reticulum stress pathways activation, inducing cellular change and increased reactive oxygen species and lipid peroxidation [70].

Endometrial cancer survivors have an overall higher cardiovascular risk, even after finishing chemotherapy. These patients have a higher incidence of arterial hypertension and vascular disease. Moreover, endometrial cancer survivors had a 47% higher risk of heart disease compared with patients with no endometrial cancer history [71]. This higher risk can be caused by early menopause induced by hormonal treatment (which is associated with increased cardiovascular risk) and surgical treatment by hysterectomy with bilateral adnexectomy (except for stage IA G1 endometrial cancer, according to the ESMO clinical practice guidelines) [72]. The cessation of estrogen cardiovascular protection leads to vascular dysfunction, arterial hypertension, and redistribution of body fat [73]. Thus, patients with Lynch syndrome-associated endometrial cancer are at significant risk of cardiovascular disease because of various factors – early menopause – surgical hormonal, and chemotherapy.

To prevent cardiotoxicity development in cancer patients, the new guidelines for Cardio-oncology recommend risk stratification tools, such as the HFA-ICOS risk stratification [20]. Risk factors and their stratification in VEGFi therapy are exemplified in Table 1.

CONCLUSION

Lynch syndrome-associated cancers are aggressive and require significant chemotherapy regimens. Some effects are transient; however, some may be permanent. This is an important reason for the necessity of introducing a consistent interdisciplinary team that includes a cardiologist and an oncologist in the management of oncological patients, especially young ones, such as patients with Lynch syndrome.

Abstract: *The purpose of this article is to investigate the role of emotional regulation (ER) as a process underlying a variety of symptoms associated with Lynch syndrome (depression, anxiety, fear of cancer recurrence (FCR), insomnia, fatigue, pain, and subjective cognitive difficulties in patients with Lynch syndrome. Firstly, we provided an overview of the main psychopathological symptoms found in cancer patients and their impact, and then an overview of emotional regulation strategies and discussed the main impact ER strategies have on cancer patients, especially emotional suppression and experiential avoidance, as found in evidence-based studies. Recent research has shown that two ER strategies generally considered maladaptive, emotional suppression and experiential avoidance were significantly associated with higher levels of anxiety, depression, FCR, fatigue, and cognitive difficulties. We propose that experiential avoidance and emotional suppression may be common transdiagnostic mechanisms for a common set of psychological symptoms in Lynch syndrome patients, a hypothesis to be tested in a future study***.**

Keywords: *emotional regulation; experiential avoidance; emotional suppression; Lynch syndrome*

INTRODUCTION

With genetic diagnosis being available for a high number of hereditary syndromes the number of families with knowledge about hereditary cancer is also increasing. Lynch Syndrome, also known as hereditary non-polyposis colorectal cancer (HNPCC), is a multi-cancer syndrome caused by inherited DNA mismatch-repair gene mutations that pose particularly high risks for colorectal, gynecological, stomach, small bowel, pancreas, hepatobiliary tree, brain and urinary tract cancers.

Genetic counseling provides information about traits, possibilities, and recommendations for cancer-preventive programs.

Particularly, in Lynch Syndrome, the diagnosis is requested by most members of a family and it is beneficial since, for example, colonoscopy reduces morbidity and mortality in colorectal cancer [1-5].

Family members with hereditary cancer often experience death from cancer from close relatives and it can be assumed this may represent a burden for them with studies addressing psychological well-being in those individuals with increased risk of developing cancer. Studies are primarily focusing on genetic counseling time framework and found increased levels of distress and anxiety with the return to baseline 6-12 months after the diagnosis.

10% maintained distress related to the diagnosis after the same period [6-8]. Meanwhile, there are few studies concerning the psychological impact of Lynch Syndrome diagnosis.

Thus, our research questions focused on highlighting the main psychological symptoms that are associated with cancer diagnosis and specifically, Lynch Syndrome patients. At the same time, we wanted to assess the literature concerning the main emotional regulation strategies used by patients with cancer and/or Lynch Syndrome patients.

After assessing the main variables described above our main research question concerned the possible relationship between specific emotional regulation strategies and psychopathological symptoms in cancer patients and, specifically, in Lynch Syndrome patients.

MATERIALS AND METHODS

Studies included in the review consisted of published English-language peer-reviewed articles focused on assessing correlations between various emotional regulation strategies and mental health outcomes in patients diagnosed with Lynch Syndrome. We utilized the following databases: Google Scholar, Elicit, PsycINFO, and conducted electronic searches from June 2023 to August 2023, examining articles published at any time prior to June 15, 2023. Searches were conducted with terms related to Emotional Regulation strategies (i.e., “emotional regulation,” “suppression”, „experiential avoidance” and Lynch Syndrome patients (i.e., “Lynch Syndrome,” “cancer genetic testing” “Lynch Syndrome mental health”).

The concepts of „emotional regulation strategies” and „Lynch Syndrome diagnosis” were scarcely mentioned throughout the literature thus we included broader concepts like „cancer patients”, „emotional regulation in cancer patients” and „mental health in cancer patients” to attain a broader perspective on our primary objectives. All published articles found using the above search terms and deemed to be related to the topic of focus were included based on their relevance and familiarity with the hypothesis asked.

EMOTIONAL REGULATION (ER) AND LYNCH SYNDROME

ER may play a significant role in the mental adjustment of individuals diagnosed with Lynch syndrome. It may represent a key factor in mental adaptation to this diagnosis in various contexts as follows: a) coping strategies, where ER helps individuals with Lynch syndrome cope with the stressors within the disease.

Communal coping, which involves perceiving stressors as a shared problem and mobilizing adaptive resources together, can be an effective strategy for families affected by Lynch syndrome [9]; b) psychopathology and well-being where ER strategies can be adaptive or maladaptive depending on their function, context, and timing. Effective ER can contribute to better mental well-being and reduce psychopathological symptoms in individuals with mental disorders [10,11].

Also, ER can help individuals manage the psychological impact of the condition and maintain a better quality of life; c) social support and emotional expression, where ER is closely linked to situations, for example, when individuals perceive their social network as less responsive, they may suppress their emotions and not express them openly. This emotional suppression can contribute to distress in individuals facing an increased genetic risk of cancer [12]; d) trauma and emotion regulation. Previous research suggests that trauma, including early life stress, can affect the acquisition of appropriate ER skills. Individuals who have experienced trauma may have difficulties understanding and regulating their emotions. This can have implications for individuals with Lynch syndrome who may have experienced traumatic events related to their condition [13,14].

Overall, emotional regulation may play a crucial role in the mental adaptation of individuals with Lynch syndrome. It may help them cope with stress, maintain mental well-being, navigate social support, and manage the psychological impact of their condition. Developing effective emotional regulation skills can contribute to better mental health outcomes for individuals with this diagnosis.

MENTAL HEALTH AND LYNCH SYNDROME

Lynch syndrome can have a significant impact on the mental health of affected individuals and their families. Individuals, whether they have had cancer, may experience an increase in depression and anxiety scores post-disclosure [15]. A study found that 10-12% of Lynch syndrome carriers displayed depressive symptoms [16].

Long-term psychosocial and behavioral adjustment in individuals receiving genetic test results in Lynch syndrome showed that participants who underwent genetic testing for Lynch Syndrome (LS) had higher levels of anxiety and depression compared to those who did not undergo testing [17]. Also, individuals with Lynch syndrome may experience long-term psychosocial and behavioral adjustment issues [17]. This can include difficulties with coping, emotional regulation, and social support.

An important part of the mental health impact factors is represented by the structure of emotional support networks in families, which can be affected. Communal coping, which involves perceiving stressors as a shared problem and mobilizing adaptive resources together, can be an effective strategy for families affected by LS [17,18]. However, if individuals perceive their social network as less responsive, they may suppress their emotions and not express them openly. This emotional suppression can contribute to distress in individuals facing an increased genetic risk of cancer, such as LS [19]. Regarding a study found that individuals with LS may have a lower sense of coherence (SOC) and self-concept. Low SOC has been found to be associated with anxiety and depression after genetic counseling [20].

In conclusion, LS can have a significant impact on the mental health of affected individuals and their families. It can lead to depression, anxiety, difficulties with psychosocial and behavioral adjustment, social support, and self-concept.

PSYCHOPATHOLOGICAL SYMPTOMS ASSOCIATED WITH CANCER AND CANCER TREATMENTS

Anxiety and depression

In the oncological context, psychological suffering is defined as a multifactorial and unpleasant experience of a psychological nature (either cognitive, affective, or behavioral), social or spiritual, which may affect the ability to cope effectively with cancer, physical symptoms, and its treatments [21].

Psychological suffering occurs along a continuum that varies from feelings of vulnerability, sadness, and concern about the disease, which are normal responses to cancer, to problematic and disabling symptoms such as depression, anxiety, and adaptive disorders [21].

Symptoms of a depressive disorder include a depressed mood and/or decreased interest in or pleasure in activities, accompanied by fluctuations in weight or appetite, sleep disturbances, psychomotor agitation or slowness, fatigue or loss of energy, feelings of worthlessness or excessive or inappropriate guilt, concentration difficulties, and recurring thoughts of death or suicidal [22].

Anxiety disorders, on the other hand, manifest themselves in the form of cognitive disorders (e.g., attentional bias toward threatening stimuli), affective (e.g., anxiety, nervousness), behavioral (e.g., avoidance), and physical (e.g., muscle tension). Symptoms of depression and anxiety are often experienced on a transient basis, which is part of the normal process of adapting to cancer. However, the simultaneous occurrence of several symptoms (5 of 9, including one of the first two in the case of major depression), accompanied by clinically significant distress or marked impairment of the person's social, occupational, or other functioning, indicates the presence of a psychological disorder [22].

When a person experiences excessive psychological suffering in relation to what is considered normal or which significantly affects normal functioning, within three months of exposure to an identifiable stressor, such as LS, an adaptation disorder may be diagnosed. Adaptation disorder may be accompanied by depressive and/or anxiety symptoms (but may not meet the criteria for a depressive disorder and/or anxiety or other emotional and behavioral disorders [22].

Prevalence

According to a meta-analysis of 70 studies of 10,071 patients with different types of cancer, 38% of patients suffered from depression, an anxiety disorder, or an adjustment disorder [23]. In comparison, the annual prevalence of major depressive disorder in the general population is 4% [24].

Fear of recurrence/Fear of cancer recurrence (FCR)

It is a more specific form of anxiety or concern about the idea that the disease/cancer returns or progresses [25]. In the original formulation [26] FCR is not an exclusively emotional phenomenon. It is rather a multidimensional construct in which the emotion of fear can result from negative interpretations or cognitions about cancer, which in turn would be triggered by certain internal causes (for example, physical symptoms) or external (for example, a cancer television program [26,27,28]. FCR can lead to maladaptive reactions (for example, anxiety concerns, avoidance, self-examination, and the search for excessive reassurance), which in turn are likely to increase the extent of this FRC [26]. Most patients consider this symptom to be a major concern and declare that they have not received enough help to manage it [29].

Prevalence

Due to the lack of consensus on the definition and measurement of FRC, the prevalence rates of this symptom vary considerably in the literature, ranging from 24% to 70% in breast cancer patients [30,31]. FRC is reported to be higher in younger patients, who have more physical symptoms related to cancer or its treatment, or who have a less favorable prognosis (head or neck cancer, cancer recurrence, more advanced stage of cancer) [32,33].

Fatigue

Several authors identify this symptom as being the most reported one in relation to cancer and its treatments, regardless of the location or treatment received [34]. Fatigue is present during the entire course of the disease [35]. The most commonly used definition of cancer-related fatigue is that provided by the National Cancer Comprehensive Network (NCCN), which describes fatigue as a subjective and persistent feeling of exhaustion associated with cancer or oncological treatments that is disproportionate to activity level (the level of daily activity) and that does not subside with rest and interferes with usual daily activities [35,36]. Fatigue affects between 38% and 84% of breast cancer (female) patients during cancer treatment and up to 40% after treatment ends [37,38].

Insomnia (I)

This is the most reported sleep disturbance in cancer patients [39]. It is characterized by dissatisfaction related to sleep or sleep quality, which may include difficulty falling asleep, maintaining sleep through the night, or waking in the morning with an inability to fall asleep again [22]. When symptoms of insomnia are severe (minimum 30 minutes to fall asleep or nighttime awakenings) occurring at least 3 nights per week and more than 3 months and recurring despite adequate opportunities for sleep and eliciting marked distress or significant impairment in functioning, then a sleep disorder may be assumed [22]. Insomnia can occur independently (primary insomnia) or in comorbidity with another sleep disorder, with another psychopathological disorder (e.g. depression), or can be related to the effects of a substance (e.g. caffeine) or to a disease such as cancer (comorbid insomnia).

Prevalence in the overall population, 30% of people have insomnia symptoms, while 10-15% have insomnia syndrome [40,41]. In breast cancer patients, these rates range from 16% to 58% for insomnia symptoms and 26% to 46% for insomnia syndrome [42,43].

Pain (P)

Pain is a multifaceted phenomenon resulting from a complex interaction between different physiological (e.g. tissue damage), psychological (e.g. psychological stress related to pain), cognitive (e.g. the meaning attributed to pain), and social factors. Pain can be caused by the tumor itself, by its metastases (e.g., bone), but also due to oncological treatments [44,45].

Prevalence

Between 44% and 64% of breast cancer patients report pain during or after their oncological treatment [46,47]. Pain is thought to increase with disease progression, affecting up to 64% of patients with advanced or terminal cancer. More than a third of patients who experience cancer-associated pain describe its intensity as moderate or severe [47].

Cognitive difficulties (CD)

Cognitive functioning includes a range of functions such as verbal and non-verbal memory, language, attention and concentration, psychomotor functioning, reading, and writing. These include reasoning, problem-solving, mental flexibility, and working memory [48]. These functions are assessed either objectively using standardized neuropsychological tests or subjectively using self-assessment questionnaires. Cognitive difficulties may be related to cancer either directly (e.g. tumor or metastases located in the central nervous system) or indirectly (e.g. metabolic or endocrine abnormalities, infections, and oncological treatments such as chemotherapy; [49]. The main cognitive difficulties reported by patients following cancer treatments include difficulties in learning added information, memory problems, and decreased attention and concentration [50,51,52]. It should be noted that, in general, both objective and subjective measures of cognitive functioning in cancer patients are poorly associated with each other [53]. Moreover, subjective complaints of cognitive impairment, rather than the results of objective neuropsychological tests, are more closely correlated with depression, anxiety, and fatigue. Therefore, it seems that cognitive performance and perception of one's cognitive abilities are two different phenomena. In this study, only subjective cognitive difficulties will be evaluated.

Prevalence

Between 21% and 90% of breast cancer patients report subjective cognitive difficulties [52]. Considering all types of cancer combined, the highest proportions of cognitive difficulties are observed during oncological treatment [54]. While some results indicate that cognitive functioning returns to normal 6 to 12 months after the end of treatment [55], others suggest that cognitive difficulties may persist for up to 10 or even 20 years after the end of treatment [56].

THE IMPACT OF PSYCHOPATHOLOGICAL SYMPTOMS ASSOCIATED WITH CANCER AND CANCER TREATMENTS

Psychopathological symptoms associated with cancer and oncology therapy have consequences for patients. Depression, anxiety, fear of cancer recurrence, fatigue, insomnia, pain, and cognitive difficulties are all associated with poorer quality of life and impaired daily functioning [57,58]. The presence of certain symptoms, such as depression and fatigue, is also related to the increased use of healthcare [57]. In addition, depressive symptoms, hopelessness, fatigue, and poorly controlled pain are risk factors for early death wishes and /or suicidal thoughts and actions in cancer patients [59,60].

Emotional Regulation (ER)- concept definition and strategies

Emotional regulation (ER), which has been the subject of increasing interest in the field of clinical psychology in recent years, maybe a psychological mechanism that could contribute to the etiology of psychological symptoms associated with cancer. In fact, problems related to emotions or emotional regulation characterize about 75% of the mental disorders listed in the Diagnostic and Statistical Manual of Mental Disorders [61]. An increasing number of studies suggest that difficulties with ER play a central role in developing and maintaining psychopathology [62,63,64].

Some psychopathologies such as anxiety and mood disorders are diagnosed primarily based on emotional disorders, including a predominance of negative affect [65]. ER also influences perception and adaptation to acute and chronic pain, fibromyalgia, and chronic fatigue [66-69].

Emotional problems are also considered to be associated with insomnia. On the one hand, emotions that have not been adequately regulated during the day tend to reappear when it is time to go to bed, fueling concern and anxiety and also affecting sleep and creating hyperactivation that is harmful to sleep [70]. On the other hand, sleep problems could be harmful to the emotional regulation of the next day by creating emotional hyperactivation [71]. This suggests that emotional regulation problems could underpin several symptoms associated with cancer, a hypothesis that has not yet been studied [61].

Emotional problems are also thought to be associated with insomnia. On the one hand, emotions that have not been adequately regulated during the day tend to resurface when it is time to go to sleep, fueling concern and anxiety affecting sleep, and creating hyperarousal that is detrimental to sleep [70,71]. On the other hand, sleep problems could be detrimental to daytime emotional regulation by creating affective hyperactivity [70]. This suggests that problems with emotional regulation may underlie more symptoms associated with cancer, a hypothesis that has not yet been studied [61].

To fully understand ER, it is important to first define the concept of emotion. The definition varies greatly in the literature, but different authors seem to agree on three general points. First, emotions involve changes in the fields of subjective experience, behavior, and physiology. Second, emotions are dynamic phenomena that occur over a period of time that varies from a few seconds to a few minutes [72].

Third, the same emotion can be beneficial or harmful, depending on the context [72]. Fear, which leads to the avoidance of a potentially serious threat, and joy, which strengthens social relationships, are examples of beneficial emotions that adapt to their context [72].

Emotions are harmful when their intensity, duration, frequency or type are inadequate to the situation and when they give rise to maladaptive behaviors or cognitions.

The modal pattern of emotions [72] schematically illustrates how the situation, attention, evaluation appraisal and response follow one another. First, an emotion is directed towards a specific object: it has a trigger, or external situational antecedents (e.g. watching a sad movie) or internal antecedents (e.g. anticipation of an exam). Second, the trigger must receive the person's attention for there to be an emotional response. Third, the trigger is assessed according to the person's priorities (e.g. passing an exam, pleasing the other person). Fourth, several physiological, behavioral, and experiential systems coordinate to produce an emotional response. Fifth, emotion is flexible, meaning that it can be overridden (nullified) by other imperatives or responses to the situation. This flexibility is what allows emotion to be regulated [61].

ER refers to the strategies by which individuals influence the nature of the emotions they experience, as well as when and how they experience these emotions [61,72]. ER strategies can be automatic or controlled, conscious or unconscious, and can occur at any point in the sequence of the production of the emotional response illustrated in the modal pattern of emotion [61]. ER can be used to reduce, maintain, or even increase the intensity of an emotion [61].

ER has some similarities to coping strategies. Adaptation is defined as the cognitive and behavioral efforts that are undertaken to cope with external or internal demands deemed to exceed the individual's resources. Both ER and coping are processes for regulating affective processes [72]. However, coping is generally defined as a global reaction that occurs in response to a stress factor and includes a set of reactions aimed at both changing a stressful situation, as well as stress regulation related to the stressor. ER, on the other hand, incorporates reactions to specific emotions, both positive and negative, that occur in a variety of contexts, including stressful situations [72]. Both ER and coping are dynamic processes that change over time [73]. Nevertheless, compared to ER, which occurs more limited in time, coping is described as a process that can take place over a long period of time (for example, coping with mourning over several months). As mentioned above, ER may include both automatic and conscious processes, while coping is considered to primarily reflect conscious processes [73]. In addition, while ER strategies may occur just before an emotion is generated, (for example, by avoiding exposure to a situation), coping occurs after exposure to stress [72,73]. ER and coping would therefore be separate constructions that are partially juxtaposed, their main common ground is that they involve efforts to regulate emotions in response to stressful events or circumstances [73]. ER strategies can target different components of the emotional response, namely the experiential (subjective experience of the emotion), behavioral (e.g. facial expression specific to an emotion such as disgust, fear, or joy), and physiological (e.g. activation of the sympathetic nervous system [72]. ER strategies were classified into five groups, based on the point in the emotional response sequence at which they occur. Situation selection strategies refer to the decision whether or not to expose oneself to a situation that might elicit an emotion, (i.e.) which is the choice to avoid or go to certain places, people, or activities. Subsequently, coping strategies make it possible to act on the situation to change its emotional impact.

Attentional deployment strategies involve directing attention to a specific aspect of the situation. Cognitive reappraisal strategies involve changing the meaning of the situation that the person attributes to it in order to change the associated emotions. These four types of strategies are initiated before the emotional response is fully deployed (e.g., behavioral change or physiological activation), as opposed to the fifth type of strategy, response modulation strategies, which aim to modify the emotional response already produced.

Each type of strategy can be used adaptively or maladaptively, depending on the context in which it is used [72]. The later ER occurs in the sequence of producing the emotional response, the more effort it requires [61]. Intervention as early as possible in the sequence of producing the emotional response would make it possible to adjust the emotion more efficiently [74]. ER is maladaptive when it does not alter the emotional response in the desired way (e.g., does not reduce negative affect), when the long-term costs of a strategy (e.g., disruption of functioning, interpersonal relationships) exceed the benefits associated with short-term emotional changes, or when the strategy used is not contextually appropriate [61].

ER can be evaluated either subjectively, using self-assessment questionnaires, or objectively, using physiological indicators, such as heart rate variability. The ER strategies that have been most studied in both the general population and cancer patients are cognitive reappraisal, suppression of emotional expression, and experiential avoidance [61].

Cognitive reappraisal

Cognitive reappraisal involves changing the appreciation of a situation to reduce or increase its emotional intensity [61]. In Gross and Thompson's model, this strategy occurs before the emotional response is fully unfolded [75].

In the general population, the use of reappraisal is associated with higher levels of effectivity, lower levels of negative affect, fewer depressive symptoms, higher self-esteem, greater satisfaction with life, better interpersonal functioning, and increased well-being [61]. In patients suffering from depression, less frequent use of cognitive reappraisal has been associated with higher levels of depressive symptoms [76]. Other results indicate that this strategy moderates the relationship between stress and depressive symptoms, in that, in high-stress situations, the use of cognitive reappraisal makes it possible to regulate negative emotional states likely to lead to depressive symptoms [77]. In addition, reappraisal has a low impact on physiological activation and cognitive resources [61]. It is also associated with lower levels of inflammation and reduced risk of cardiovascular disease [78]. Therefore, cognitive reappraisal is considered a generally appropriate CR strategy [79]. Learning this strategy is also a key element of several psychotherapies, including cognitive-behavioral therapy [80]. Although several clinical trials have demonstrated the effectiveness of CBT in reducing anxiety, depression, pain, insomnia, and fatigue in cancer patients [81], the specific impact of cognitive reappraisal on a range of psychological symptoms associated with cancer has been poorly studied. Only one study investigated the association between this strategy (Emotion regulation questionnaire; ERQ) and anxiety and depression in 144 patients with different cancers [82]. Lower levels of cognitive reappraisal were cross linked to more anxiety and depression three months after cancer diagnosis. Other studies have evaluated the effect of a subtype of cognitive reappraisal, positive reassessment, which involves changing one's evaluation of a situation so as to give it a positive meaning [83].

In a prospective study of a sample of 509 women with breast cancer, the use of cognitive reappraisal was evaluated using the Cognitive Emotion Regulation Questionnaire, a questionnaire that assesses various cognitive ER strategies under stressful conditions (including positive reappraisal). Positive reappraisal and depressive symptoms were assessed five to seven days after oncological surgery (T1), and then depressive symptoms were re-evaluated one month later (T2). Higher levels of positive reappraisal at T1 were associated with lower levels of depressive symptoms at T2. In a cross-sectional study it was analyzed the effect of certain social strategies (avoidance of talking to loved ones about cancer concerns and unsupportive behaviors from loved ones) and cognitive strategies (positive reappraisal, self-esteem, and confidence in one's ability to cope with cancer; COPE inventory) on CRP and depressive symptoms in 150 women diagnosed with gynecological cancer. Self-esteem has significantly mediated the relationship between CRP and depressive symptoms. A higher level of positive reappraisal has been associated with lower depressive symptoms, but this strategy was not significantly associated with CRP [84].

Results from another cross-sectional study that included 353 patients diagnosed with breast cancer showed a weak correlation between positive reappraisal (Mini-Mental Adjustment to Cancer Scale) and cancer-related fatigue [85]. Nevertheless, this association was significant only in a multivariate analysis model that also included age, depression, and grief: the unique relationship between positive reappraisal and fatigue was not significant. Finally, in another study, positive reappraisal (COPE Inventory), positive mood (Vigor subscale of the Profile of Mood States) and psychological distress (Anger, Depression, Tension, Fatigue and Confusion subscales of the Profile of Mood States Scale) were measured in 92 breast cancer patients at three-time points, namely 20 weeks after the end of oncological treatment (T1), at 3 months (T2) and 12 months (T3). The higher levels of positive reappraisal in T1 significantly predicted an improvement in the positive mood at subsequent measurement time points in participants who had low or medium levels of positive mood at T1. Positive reappraisal did not predict psychological distress.

In conclusion, existing studies suggest that cognitive reappraisal is an adaptive and cognitively somewhat expensive ER strategy. It is associated with lower levels of psychopathology (depression and anxiety) in the general population. In cancer patients, only five studies have evaluated the possible impact of this strategy. The results are contradictory and the literature has its limitations. First, only one study specifically investigated cognitive reappraisal in this population, while the others focused on a subtype of cognitive reappraisal, namely positive reappraisal. Thus, little is known about the impact of cognitive reassessment in general on adaptation to cancer. Results in the general population suggest that this strategy may be associated with better adaptation to cancer, but more studies are needed on this question. In addition, the existing literature is limited to depression, anxiety, CRF, and fatigue. The relationship between cognitive reappraisal and other isolated symptoms (pain, insomnia, cognitive difficulties) remains unknown, as does its association with symptom clusters.

Emotional suppression (ES)

Emotional suppression is defined as an individual's effort to reduce an unwanted emotional experience. Specifically, suppression consists of inhibiting behaviors related to emotional expressions, such as facial expression (e.g., maintaining a neutral face, suppressing crying or laughing) or verbal expression (e.g., avoiding mentioning the experienced emotion) in order not to communicate to others information about the emotional states of the person [86]. This strategy also includes suppressing thoughts associated with emotional reactions [87]. Suppression is not a highly effective RE strategy and involves various short- and long-term costs. Although this strategy may reduce the subjective experience of positive emotions, it has no effect on the subjective experience of negative emotions [72]. In many cases, suppression has the paradoxical effect of increasing the negative emotions that the individual is trying to suppress [88]. Therefore, suppression is associated with important levels of negative affect, reduced levels of positive affect, poorer social functioning, and a diminished sense of personal well-being [72]. It can also lead to cognitive overload, reduced cognitive performance, and impaired memory and attention [87,88]. Suppression would be less effective and require more effort than cognitive reassessment [72]. In addition, it appears that suppression is used more frequently in people with a mood or anxiety disorder than in those without a psychological disorder [89]. Several studies also associate suppression with poorer adjustment to pain and chronic fatigue syndrome, increased risk of insomnia, higher levels of inflammation, and an increased risk of cardiovascular disease [90]. Suppression may also be associated with an increased risk of death (cancer, cardiovascular mortality, and all-cause mortality), although more studies are needed to confirm and explain this association [91]. Conversely, a good ability to flexibly regulate (i.e., suppress and enhance) the expression of joy and sadness has been associated with less interference with physical symptoms (e.g., headaches, heart problems). Although the individual using suppression seeks to reduce the intensity of the emotions felt, this strategy is often associated instead with activation of the sympathetic nervous system, manifested by changes in skin conductance and temperature as well as the pulse amplitude at the finger [72]. For example, 180 participants were asked to watch either emotionally charged or uncharged movies (sad, neutral, and funny) in the usual way or using suppression. Suppression was not associated with any physiological effect for the neutral movie, but for the amusing one, it was associated with an increase in sympathetic activity as measured by digital pulse amplitude, finger pulse transmission time, and digital temperature, and a reduction in heart rate. For the sad film, the suppression was associated with an increase in skin conductance and sympathetic and respiratory activation [92].

In cancer patients, the results of the few studies available indicate that suppression is generally associated with higher psychological distress. In a cross-sectional study previously described, higher suppression levels were associated with higher levels of anxiety and depression [82]. A study evaluated the relationship between suppression (measured with the Courtauld Emotional Control Scale), anxiety (Manifest anxiety scale), and emotional distress (Mood profile scale) in 93 women who completed questionnaires before and after being diagnosed with cancer or benign tumor to the breast. High levels of anxiety and suppression measured before cancer diagnosis have been associated with significantly higher scores of emotional distress before and after diagnosis. Of the 21 participants diagnosed with cancer, those with higher levels of suppression before diagnosis reported more psychological suffering after diagnosis. The same researchers then evaluated the effects of suppression on the negative emotions of 14 breast cancer patients on their first visit to the outpatient clinic, immediately after being diagnosed with cancer, after surgery, and at a follow-up visit three months later [93]. Participants with higher levels of suppression measured before diagnosis reported more general psychological distress, anxiety, depression, and anger at all measurement times except immediately after surgery. In addition, higher levels of suppression before diagnosis were associated with more fatigue after diagnosis. In another prospective study involving 31 breast cancer patients, suppression (Courtauld Emotional Control Scale) and psychological distress (Mood Profile Scale) were measured before surgery and between one and six months after surgery. A higher level of suppression measured before surgery was associated with more psychological distress after surgery (higher scores on stress-anxiety, depression, anger-hostility, fatigue-inertia, confusion, and total scores subscales) [94]. A similar cross-sectional association between suppression (Courtauld Emotional Control Scale) and psychological distress (all subscales of the Profile of Mood States Scale except the anger subscale) was obtained in 27 breast cancer patients who had completed their oncological treatments. High levels of suppression have also been associated with stress symptoms (for example, muscle tension, and sympathetic activation), assessed by the Calgary Stress Symptoms Inventory (C-SOSI) [95]. The results of another cross-sectional study in 139 patients in remission from various cancers for at least five years showed an association between suppression (Control Courtauld scale emotional) and higher levels of stress (Perceived stress scale), anxiety, and depression (Hospital anxiety and depression scale; HADS) and poorer adaptation to cancer (Mini-Mental scale for cancer adaptation) [96]. Suppression predicted the level of perceived stress, even after controlling depressive symptoms. However, contradictory data were also obtained. In a study that included 241 patients with different types of cancer, suppression (Courtauld Emotional Control Scale) has been associated with less self-reported psychological suffering on Distress Thermometer and HADS (total scale and depression subscale, but not on the anxiety sub-scale) [97]. To explain this unexpected result, the authors suggest that the reluctance to report psychological suffering is consistent with the use of suppression because completing a questionnaire about psychological symptoms can be perceived as an emotional manifestation. For the time being, these results have not been replicated and this hypothesis has not received empirical support.

In summary, the literature about the general population shows that suppression is associated with increased symptoms of psychological distress, pain, fatigue and insomnia, cognitive difficulties, and activation of the sympathetic nervous system. In the oncological context, several studies have investigated the relationship between suppression and psychological suffering, stress, anxiety, depression, and fatigue in a transversal and prospective manner. Therefore, these results suggest that suppression could be involved in the development of psychological and psychophysiological symptoms associated with cancer. However, the number of studies that have investigated the role of suppression in the development of cancer-associated symptoms is limited, and these studies are restricted to symptoms of depression, anxiety, and fatigue. The relationship between suppression and other symptoms that are highly prevalent in people with cancer, such as pain, insomnia, CRP, and cognitive difficulties, remains unknown. Finally, existing studies have assessed the relationship between suppression and isolated symptoms: the relationship between suppression and symptom clusters does not appear to have been studied up to the present time.

Experiential avoidance

Experiential avoidance is defined as a tendency to avoid or flee from certain psychological experiences (e.g., emotions, but also thoughts, physiological sensations, memories, impulses, and cognitions) by attempting to alter their form, frequency, or intensity, even when these attempts are futile or interfere with the individual's goals or values [98]. Experiential avoidance incorporates strategies like those used in emotional suppression. However, while emotional suppression is clearly an emotional response modulation strategy, experiential avoidance can be used at any point in the emotion production sequence [98]. In this respect, experiential avoidance is a broader concept that involves the use of strategies relevant to the five groups identified [72], namely situation selection (e.g., avoiding starting an apprehensive project), situational modification (e.g., using reassurance from a friend or family member), and situation modulation (e.g., use of a moderator to modulate the emotional response), use of reassurance by an anxious person to tolerate an uncomfortable situation), attention deployment (e.g., avoiding paying attention to thoughts, sensations or memories likely to provoke unpleasant emotions), cognitive reappraisal (e.g., attempting to rephrase a thought associated with an emotion): (e.g., "This university interview is a test of my value as a student and as a person "and replace it with "This interview is an opportunity for me to learn more about this university and see if it is really right for me") and response modulation (e.g., attempts to control verbal, behavioral, and physiological expression of emotions, including emotion suppression) [98]. In the general population, experiential avoidance is associated with poorer quality of life, poorer perceived physical health, and higher levels of general psychopathology, depression, anxiety, and substance abuse [99]. This strategy is even considered by several authors to be a fundamental mechanism in the development and maintenance of psychopathology [88]. A study evaluated the relationship between experiential avoidance (acceptance and action questionnaire), cognitive suppression and reevaluation (Emotion regulation questionnaire), and several indicators of psychological well-being and psychopathology [88]. Results suggest that experiential avoidance is a better predictor of psychological distress and anxiety symptoms than suppression and cognitive reappraisal. In addition, experiential avoidance mediated the relationship between suppression and reappraisal, on the one hand, and positive and negative daily experiences and functioning, life satisfaction and social anxiety, on the other. It is also interesting to note that the results from clinical trials suggest that reducing experiential avoidance is a significant mediator of the effectiveness of mindfulness-based therapies and acceptance and commitment therapy for several mental (e.g., stress) and physical (smoking cessation) health problems [98].

Some studies already assessed the possible influence of experiential avoidance on cancer-related symptoms [100,101] In a clinical study aimed to measure the effect of a group psychological intervention targeting anxiety, depression, and stress, 54 breast cancer patients completed the Acceptance and Action Questionnaire (AAQ-II), which measures experiential avoidance before and after the surgical intervention. A smaller decrease in experiential avoidance between the period before and after treatment predicted a weaker improvement in depressive symptoms and anxiety. Other papers have focused on acceptance, an ER strategy that is thought to be the opposite of experiential avoidance [102].

CONCLUSIONS

Although there is limited information on LS emotional regulation interventions. some studies have explored the structure of emotional support networks in families affected by Lynch syndrome and others have mapped psychosocial interventions in familial colorectal cancer. One study suggested that practitioners may assess cancer-risk-related distress before genetic testing and offer distressed individuals interventions focused on changing emotion regulation [105-107]. Another systematic review of studies involving families with BRCA1, BRCA2, and LS found that proband-mediated interventions, such as genetic counseling with additional telephone or in-person follow-up, letters, videos, and decision aids, have the potential to increase disclosure of genetic risk in families with a BRCA or LS condition [108]. However, none of these studies specifically focused on emotional regulation interventions for LS. It is worth noting that some studies have explored emotion regulation in the context of cancer survivorship more broadly. For example, researchers have called for the study of emotion regulation in breast cancer survivorship [109]. The Difficulties in Emotion Regulation Scale (DERS) and the Emotion Regulation Questionnaire (ERQ) are two tools that have been used to assess emotion regulation strategies [109]. However, these studies are not specific to LS.

Future perspectives

Cancer patients suffer from a range of psychological symptoms (depression, anxiety, CRF, insomnia, fatigue, pain, and subjective cognitive difficulties). Several authors suggest that a common psychological mechanism may contribute to the development and maintenance of symptoms, but no study has investigated this hypothesis so far. One possible underlying mechanism is ER, which has been the subject of increasing interest in clinical psychology in recent years. One possible underlying mechanism is RE, which has been the subject of increasing interest in clinical psychology in recent years. Previous work has shown that two RE strategies, emotional suppression (inhibition of emotion-related thoughts and behaviors, such as facial expression of emotions) and experiential avoidance (avoidance of feelings, physical sensations, and emotion-related thoughts), have been associated with anxiety, depression, and fatigue in patients treated for cancer. In contrast, cognitive reappraisal, i.e. changing the meaning associated with a situation to alter its emotional load, appears to be associated with better adaptation to cancer, in particular with fewer depressive and anxiety symptoms. Therefore, studies are needed to determine the role of ER as a common psychological mechanism for a broader set of cancer-associated symptoms, both cross-sectionally and prospectively. The study of psychological mechanisms that may underlie clusters of symptoms associated with cancer is relevant both theoretically and clinically. From a theoretical point of view, it is necessary to better understand why and how these symptoms develop. Clinically, several authors have emphasized that it is vital to understand the processes underlying the emergence of symptom clusters in order to provide more effective treatments [110]. For example, transdiagnostic psychological treatments for psychopathologies (for example, anxiety and depressive disorders) are innovative interventions that are of growing interest to psychologists and clinicians. These treatments make it possible to treat multiple comorbid psychological disorders simultaneously because they target the affective, cognitive, and behavioral processes underlying the disorders (e.g., avoidance, rumination, and suppression, which are found in a variety of anxiety and mood disorders), rather than targeting each disorder individually [111]. The effectiveness of several transdiagnostic treatment protocols developed for mood and anxiety disorders has received a great deal of empirical support [112]. However, these protocols cannot be applied directly to cancer patients, as they do not include certain symptoms common to this population (e.g., CRF, fatigue, pain, insomnia, and cognitive difficulties).

Identifying a mechanism underlying psychological disorders in LS would be the first step in adding real help to classical treatments.

Author Contributions

ML and CGI contributed to the conception, and structure of the paper, and contributed to the analysis, and interpretation of available literature. FG and CGI contributed to the development initial draft. ML and FG reviewed and critiqued

the output for important intellectual content. All the authors contributed to the article and approved the submitted version.

Abstract: *Lynch syndrome (LS) is one of the most common inherited cancer predisposition syndromes and the most important cause of hereditary colorectal and endometrial cancers. It is inherited in an autosomal dominant pattern, caused by a pathogenic germline variant in one of the mismatch repair (MMR) genes (MLH1, MSH2, MSH6, or PMS2), which encode proteins responsible for maintaining genome stability. A defective MMR system confers an elevated risk of developing certain types of cancer, at a younger age than in the general population and at a high rate of multiple primary neoplasia. Lynch syndrome is not just one disease, but a collection of different subtypes of underlying molecular aspects with specific clinical implications. A better understanding of these subgroup profiles could offer better care for each patient, leading to more personalized risk-reduction and surveillance strategies. Lynch syndrome is a frequent but yet underdiagnosed condition that needs multidisciplinary increased awareness for correct diagnosis and management. The aim of this review is to provide a summary of available literature data on the genetic aspects of Lynch syndrome together with geno-type-phenotype correlations and its clinical implications in the detection, genetic counseling, genetic testing, risk stratification, and management of this condition*.

Keywords: *Lynch syndrome; cancer predisposition; hereditary cancer; mismatch repair deficiency*

INTRODUCTION

Cancer is a disease of the genome that originates from complex interactions between various genetic, epigenetic, and environmental factors. Even though most of the genetic alterations in cancer are acquired somatic events leading to sporadic cancers, common and rare germline variants have important effects on tumor development [1,2].

About 5-10% of all cancers are hereditary. In those cases, a major inherited genetic risk factor could be identified through molecular genetic testing [3,4].

Colorectal cancer is the second most common type of cancer (after breast cancer) and the second cause of cancer death (after lung cancer) [5]. Approximately 20% to 30% of colorectal cancer cases could be associated with genetic factors and hereditary predisposition syndromes constitute 3% to 5% of all cases [3].

Lynch syndrome is the most frequent cause of hereditary colorectal cancer that accounts for 1%–3% of all colorectal cancer diagnoses [6].

According to Globocan estimated data, the burden of all types of cancer will increase in our country as well as in the entire Europe by 2040, including colorectal cancer [7]. Therefore, even if there seems to be a small proportion of hereditary causes, given the high incidence of cancer, a significant number of selected patients should benefit from hereditary cancer risk assessment, genetic counseling, and genetic testing for a correct diagnosis and management.

LS affects 1 in 279 individuals predisposing to colorectal, endometrial, ovarian, stomach cancers, and other malignancies at an earlier onset age than in the general population and at a high rate of multiple primary cancers [8,9]. It still remains an underdiagnosed condition despite all the recommendations for the identification of LS cases [10,11].

MOLECULAR GENETICS OF LS

Microsatellites, or short tandem repeats (STRs) are structures consisted of one to six nucleotides structures dispersed all over the genome, with a highly variable number of repetitions [12]. At this level, the DNA polymerase enzyme is prone to errors during DNA replication. MMR proteins are important in the recognition and correction of mispaired nucleotides, small insertions, or deletions generated by slippage of DNA polymerase [12].

A compromised or defective MMR system leads to microsatellite instability (MSI) and prone DNA to the accumulation of somatic mutations that often promote cancer development [9]. It has been demonstrated that the presence of MSI increases the mutation rate to 100-fold [13,14].

Immunohistochemical (IHC) staining of the MMR proteins and molecular testing of microsatellite instability by polymerase chain reaction (PCR) constitute the basis for the identification of MMR deficiency [15]. MSI and/or immunohistochemical loss of expression of MMR proteins could be identified frequently in colorectal and endometrial cancers and represents hallmarks for Lynch syndrome [16]. Alterations of MMR genes result in LS-associated tumors lacking the IHC expression of the corresponding MMR protein [6].

Since 2009, The Evaluation of Genomic Applications in Practice and Prevention (EGAPP) Working Group recommended testing all colorectal cancer cases for MSI or MMR deficiency through immunohistochemistry as a screening method for LS [17]. Furthermore, the National Comprehensive Cancer Network (NCCN) now recommends universal testing of endometrial carcinomas for MMR proteins/MSI [18,19]. Although being important red flags for Lynch syndrome, IHC loss of expression of MMR proteins and/or microsatellite instability could not differentiate between germline and somatic origin of the defects [9].

Germline and somatic defects of the MMR genes

Mismatch repair deficient tumors may develop from acquired, somatic events in sporadic cancers or in the context of a cancer predisposition syndrome that necessitates a genetic defect of a germline origin, present from birth in all the cells of an organism [20].

LS is caused by a pathogenic heterozygous germline variant in one of the mismatch repair (MMR) genes (MLH1, MSH2, MSH6, or PMS2), which encode proteins responsible for maintaining genome stability [8].

A deficient MMR system determined by a pathogenic constitutional variant of one allele requires a second somatic hit in the wild-type (normal) allele in order to confer the cell a mutator phenotype and MSI [13,15]. This second somatic defect could be acquired through a two-hit inactivation process (based on Knudson’s two-hit hypothesis for tumor suppressor genes) or by other mechanisms such as epigenetic inactivation that may confer haploinsufficiency [21].

Despite presenting as a recessive condition at the cellular level, Lynch syndrome displays an autosomal dominant pattern of inheritance [9].

Most of the MMR variants causing LS are inherited from one parent [22,23]. De novo occurrence of MMR mutations was described but appears to be a rare presentation [24]. One study focused on determining the frequency of these cases reported that 2.3 percent of LS diagnoses occurred due to de novo germline variants [24].

Nevertheless, MSI/MMR deficiency may be attributable to somatic events/biallelic somatic inactivation [20]. For example, 15% of MSI-high/MMRd colorectal tumors are determined by hypermethylation of MLH1 promoter on both alleles (homozygous), associated with somatic BRAF V600E mutated status [16,25]. Therefore, MLH1 promoter hypermethylation analysis and/or BRAF V600E variant testing should be performed in tumors lacking MLH1 protein expression prior to germline testing to assess for sporadic origin of the MSI [23,26].

A unique somatic positive methylation result without BRAF testing in colorectal cancer could not exclude a predisposition syndrome caused by germline hypermethylation of MLH1 [23]. Although rare, this mechanism has been described and some authors recommend MLH1 constitutional epimutation testing using normal tissue in cases with methylated MLH1 that fulfil the revised Bethesda guidelines [23,27]. Similarly, just a BRAF V600E negative result could not differentiate between constitutional epimutations and germline mutations of MLH1 [23,27].

In endometrial tumors, the usefulness of BRAF testing is unclear [28]. MLH1 promoter methylation analysis is important in discriminating between somatic and inherited cases. Nevertheless, cases of coexistence of both MLH1 promoter hypermethylation and MLH1 germline mutations have been described to such an extent that Lynch syndrome could not be completely excluded in the case of positive somatic methylation of MLH1 [28].

On the other hand, the presence of two germline (homozygous or compound heterozygous) MMR defects give rise to a distinct phenotype, constitutional mismatch repair deficiency syndrome (CMMRD) a very rare presentation, with an autosomal recessive inheritance and severe clinical implications. In these cases, MMR deficiency could be encountered in any of the normal tissues of the patients, not just in the tumor cells [21].

Germline genetic testing and genetic spectrum of LS defects

Genetic germline testing in patients or healthy individuals at a high risk of carrying a pathogenic variant in one of the MMR genes is a mandatory step in the diagnosis of Lynch syndrome.

Approximately 50% of Lynch syndrome cases are determined by germline pathogenic variants in MLH1 and 40% are caused by MSH2 defects. MSH6 gene is responsible for 7-10% of LS cases and PMS2 accounts for fewer than 5% of cases [23]. In a small proportion of cases (1-3%), LS is caused by a deletion in the EPCAM (epithelial cell adhesion molecule) gene that confers loss of expression of the MSH2 gene due to hypermethylation of its promoter [23,29]. Other rare mechanisms that could be involved in the pathogenesis of LS are germline or constitutional epigenetic silencing of one of the MMR genes present in normal tissues [9,30,31].

Most of the germline defects could be identified through sequencing of the DNA or deletion/duplication assays. In contrast, epimutations are a particular type of genetic alterations that do not alter the DNA sequence but determine the transcriptional silencing of active genes [32].

Germline epimutation occurs in the germ cells, is maintained in fertilization and embryonic development, and is present in all the cells of an individual. In contrast, constitutional epimutations arise in the early stages of embryonic development, inducing a mosaic of affected and unaffected somatic cells [31]. This separation interferes with the inheritance of epimutations. Germline epimutations could be reversible between generations depending on the gender of the affected parent [33]. Studies have shown that epimutations could be inherited from the mother because there is unlikely to be lost in oogenesis whilst they disappear during spermatogenesis [31]. On the contrary, constitutional epimutations are not inherited [31]. Epigenetic silencing could also be inherited when determined by a secondary germline defect in another gene within their vicinity [30,33,34].

Germline or constitutional MLH1 and MSH2 epimutations have been described in some cases although negative for germline defects in the MMR genes [30,33–36]. The methylation of MHS6 and PMS2 genes has never been described in the literature [37].

The pathogenic spectrum of MMR variants in Lynch syndrome includes missense, nonsense, frameshift, or splice site mutations, although copy-number variants and structural rearrangements have also been described [6,23]. Therefore, to cover the most frequent alterations responsible for LS, genetic germline testing should include DNA sequencing and copy-number analysis of MMR genes as well as copy-number variations (CNVs) detection of the EPCAM gene. This approach can detect up to 99% of LS causes [23]. Testing for germline or constitutional epimutations requires different types of genetic analyses that are not routinely included in the diagnostic approach of Lynch syndrome [30]. Molecular testing of PMS2 is technically challenging considering the presence of multiple highly homologous PMS2 pseudogenes as well as balanced large rearrangements [23,38,39]. Additional analyses may be required to cover all of the genetic alterations in this gene [38,40].

Over the last few years, next-generation sequencing (NGS) testing costs and turnaround time significantly decreased. [41]. Available multigene panels comprising the MMR and EPCAM genes represent a comprehensive and more efficient testing approach than single-gene testing [19,23]. Different laboratories now offer a lot of commercial NGS panels for patients suspected of Lynch syndrome or even larger panels for hereditary colorectal cancer predisposition. These assays may present small differences in terms of performance characteristics and limitations [41].

Interpretation of genetic results

Next-generation sequencing does not provide a simple positive or negative type of results. High-throughput sequencing, also known as NGS opens up a large amount of data. That comes up with challenges in interpretation and understanding the clinical significance of the identified sequence variants [42,43]. More than 15,000 different variants were reported in the MMR genes [23].

The American College of Medical Genetics and Genomics (ACMG) guidelines provide a classification of genetic variants into five categories of interpretation: Pathogenic (P), Likely pathogenic (LP), Uncertain significance (VUS), Likely benign (LB), and Benign (B) depending on a series of criteria [43,44]. In addition, laboratories should use a uniform reporting nomenclature as a clear, common language regardless of language or country of origin [43].

Benign and likely benign variants are considered harmless and do not require additional intervention. Pathogenic and likely pathogenic variants conversely, entail specific recommendations for the prevention and surveillance of Lynch syndrome-associated malignancies and enable cascade-testing of at-risk family members and family planning strategies [22].

Besides its recognized clinical utility, very often NGS brings to light variants of uncertain significance (VUS), a challenging, grey area of results with a high potential of misunderstanding [45,46]. A VUS result means that at the time of reporting, there is insufficient populational-based or functional evidence to determine the pathogenicity of the variant or there is conflicting data in the databases or the literature about the variant's role in the disease [45,46].

As the databases and the literature are enriched with relevant data, a VUS could be reclassified into pathogenic or benign. In addition, family segregation analysis (genotyping the family members to evaluate if they have the same variant) and assessing for de novo occurrence could aid in the reclassification process [43]. Furthermore, in the process of assessing the pathogenicity of a variant, a detailed patient's phenotype is very important to be provided by the ordering clinician [43,44].

ACMG stated that "a variant of uncertain significance (VUS) should not be used in clinical decision-making" and efforts should be made to reclassify the variant into pathogenic or benign [43]. A large retrospective study that included 1.45 million individuals tested for hereditary cancer risk reported that 7.7% of unique variants of uncertain significance were reclassified [47]. Among these, 91.2% were downgraded to benign or likely benign variants 8.7% were upgraded to pathogenic or likely pathogenic variants and the median time for reclassification was less than 2 years [47].

CLINICAL SPECTRUM OF LS-ASSOCIATED MALIGNANCIES AND GENOTYPE-PHENOTYPE CORRELATIONS

Lynch syndrome is associated with an increased lifetime risk for colorectal and endometrial cancer, as well as for other extracolonic malignancies (gastric, small bowel, pancreatic, hepato-biliary, prostate, ovarian, skin, central nervous system or upper urinary tract neoplasia) [10,21].

The risk of developing breast cancer is highly debated. There are conflicting results in the literature, still, some studies point out that pathogenic variants in MSH2/PMS2 may confer a 2 to 3-fold increased breast cancer occurrence [48–50].

Lynch syndrome is a highly heterogeneous disease with important variability within the molecular germline defects, somatic profile of the tumors, as well as the onset age of cancer diagnosis and penetrance for different types of cancer [6,15].

Genotype-phenotype correlations provide individualized surveillance protocols according to subsequent genetic alteration.

Mutation carriers of MSH2 and MLH1 have a significantly higher lifetime risk of cancer compared to MSH6 or PMS2 carriers. The lifetime cancer risk by age 70 for MSH2 is 57-80%, followed by MLH1 with 59-65%, 25% for MSH6, and 25-30% for PMS2 [21]. Moreover, MSH6 and PMS2 mutation carriers display higher ages of onset for different types of LS-associated cancers [21]. Therefore, MSH6 and PMS2 confer a milder phenotype and reduced penetrance of cancer compared with MLH1 and MSH2 carriers. This fact has important implications in surveillance strategies according to each gene's corresponding risk. Better tolerability of MSH6 and PMS2 variants compared to MLH1 or MSH2 could also explain their frequent presentation in a biallelic state in CMMRD syndrome [22]. In addition, variability regarding age at first cancer diagnosis is observed between families with the same affected gene as well as within the same family affected by the same variant [51]. A variety of environmental and genetic factors contributing to the different onset ages of cancer in Lynch syndrome families have been proposed [52].

Genetic anticipation, a phenomenon characterized by progressively earlier age at the onset of a hereditary disorder and/or increased severity in subsequent generations, has also been described in Lynch syndrome [51–53]. It was also observed that patients with de novo mutations have a younger age of onset than those with an inherited variant [24].

LS patients also manifest a variable expressivity depending on MMR underlying the affected gene. Particularly, mutation carriers of MLH1 display the highest risk of developing colorectal cancer among all patients diagnosed with LS, and MSH2 carriers have the most elevated risk for extracolonic malignancies [10,21]. A large study based on data from the prospective Lynch syndrome database (PLSD) reported that the cumulative risks for colorectal cancer at 70 years of age are 46% for MLH1 carriers, 35% for MSH2, 20% for MSH6 and 10% for PMS2. The corresponding risks for developing endometrial cancer were 34%, 51%, 49% and 24% [54].

Muir-Torre syndrome is a phenotypic variant of LS most frequently determined by MSH2 germline defects. It is characterized by a high incidence of cutaneous sebaceous tumors (sebaceous adenomas/carcinomas and keratoacanthomas) [9].

Turcot syndrome, another phenotypic variant of LS, describes patients presenting with colorectal cancers and central nervous system tumors (glioblastomas) [6,9]. However, Turcot syndrome could also be part of the familial adenomatous polyposis (FAP) syndrome caused by an APC germline defect when colorectal cancer is associated with medulloblastoma [6,9,21].

Besides these larger associated risks for any of the MMR genes, it was observed that even for the same type of cancer, different mutational patterns were described in the same organ partly depending on the germline MMR-affected gene [15].

According to the "three-pathway model of carcinogenesis", LS colorectal cancers could develop from MMR-proficient adenomas, MMR-deficient adenomas, or MMR-deficient crypts [15]. NGS analyses of colorectal tumors in LS have shown highly heterogenous molecular somatic defects that could be associated with different affected MMR genes [2,15] For example, colorectal cancers due to MLH1 defects have been associated frequently with CTNNB1 mutations that could explain nonpolyposis immediate invasive growth through MMR-deficient carcinoma pathway resulting in interval carcinoma presentation [15]. On the contrary, PMS2-associated colorectal tumors do not harbor CTNNB1 defects and do not show interval colorectal cancers [15].

This variability shows that LS is not just one disease with a unique profile. It could be divided into distinct subgroups, with different associated risks and surveillance strategies depending on the germline MMR-affected gene [15] A better understanding of these subgroup profiles could offer better care for each patient, leading to more personalized surveillance strategies.

STRATEGIES FOR DIAGNOSIS OF LYNCH SYNDROME

The evaluation of individuals at high risk of carrying one LS pathogenic variant could encompass the following scenario:

- traditional testing strategy based on clinicopathological criteria (Amsterdam I/II criteria and Revised Bethesda guidelines)
- personal history of MMR-deficient tumor;
- increased risk for LS based on clinical prediction models;
- presence of confirmed LS pathogenic variant in the family [9,10,42].

In the 20th century, before the discovery of the genetic background of LS, family history of cancer represented the main tool in identifying familial aggregates of malignancies [9].

Amsterdam criteria (I and II) and Bethesda Guidelines, based on family and personal history of cancer and age of cancer onset were used to identify individuals eligible for molecular analysis [3,10]. Requiring three or more family members diagnosed with cancers from the LS spectrum at an early age, Amsterdam criteria were very stringent [3,22]. This method of screening targeted families with highly penetrant and dominant cancers, thus being less sensitive in detecting LS cases determined by pathogenic MSH6 or PMS2 variants [55,56]. Subsequently, less stringent Bethesda Guidelines (based on patient and/or family history of LS cancers and MSI-high pathologic features of colorectal tumors) were formulated to provide wider clinical criteria for screening of LS [3,9,22,57].

Despite these family-history-based prediction tools, just some selected patients were offered testing for LS [55,58]. Studies have shown that families meeting one of the clinical criteria have 82% sensitivity and 77% specificity in detecting LS and that Bethesda guidelines may miss up to 25% of LS cases [9,59].

Later on, because of the low sensitivity of family-history-based clinical criteria, “universal tumor screening” of all newly diagnosed colorectal cancer cases for MMR-deficiency by immunohistochemistry testing or for MSI was proposed as an alternative strategy to guide Lynch syndrome evaluation [3,10]. This approach demonstrated improved sensitivity compared to revised Bethesda guidelines [3]. Afterward, universal tumor testing was expanded to include recommendations for screening all endometrial cancers for LS if not limited by resources to maximize the sensitivity of LS detection [3,58,60].

Computational prediction models such as PREMM5, MMRPro, and MMRPredict represent effective tools in guiding germline testing, especially in the absence of available tumor tissue [8,57–59]. These models incorporate information like family history of cancer in order to estimate the likelihood of carrying MMR pathogenic variants [57,58]. For example, PREMM5 provides comprehensive risk estimation for all MMR genes [61]. Referral for genetic evaluation and germline genetic testing is recommended for individuals with overall predicted probability scores ≥2.5% [61].

If a pathogenic family variant is known, genetic testing for both affected and at-risk family members should be performed targeting that particular mutation [9,42]

Individuals meeting any of these scenarios should be referred for genetic counseling and genetic testing [42].

GENETIC COUNSELING IN LS FAMILIES

Patients following any germline genetic testing should receive appropriate pre-test and post-test genetic counseling [42].

Collecting detailed personal and family medical history (with at least three-generation pedigree on each side of the family) is an important step in understanding hereditary risk in a family [42,57]. Comprehensive cancer risk assessment should be focused on the type of diagnosed cancers in the family members (colorectal cancer, endometrial cancer, and other extracolonic LS-associated malignancies) as well as subtypes, pathology details, age of diagnosis, age of death, and causes of death, details about the patient or family’s country of origin or ancestry, and any known possible consanguinity [42]. Still, a negative family history of LS cancers should not exclude a possible LS diagnosis. De novo occurrence of a germline variant, constitutional epimutations, reduced penetrance, cancers not yet manifested in carriers, or early death of family members by other causes could represent sources of negative family history in LS cases [24,31,62]. Therefore, overreliance only on family history of LS-associated cancers to guide the selection of families for LS testing could contribute to general underdiagnosis of this condition [22,24].

Universal testing of colorectal and endometrial tumors could efficiently identify symptomatic patients at risk of Lynch syndrome. Genetic counseling is not required prior to testing of the tumor tissue for MMR proteins/MSI, but if a positive screening test result is obtained, patients should receive specialist counseling [42,58].

Pre-test genetic counseling is focused on providing essential information about the possible outcomes of germline testing, including positive or negative results as well as variants of uncertain significance (VUS), unexpected incidental findings, and limitations of the test [42,57].

Education of the patient or asymptomatic at-risk individuals on possible management options depending on the genetic test result, inheritance patterns, heterogeneity of the disease, penetrance, and variable expressivity helps in the informed, voluntary decision-making process [9,42,57].

Genetic testing should be performed after obtaining informed consent in individuals at high risk where a positive result will impact the medical management of the case and/or their family members [4,42,58].

After disclosure of results, post-test genetic counseling is highly recommended in order to explain genetic results and their implications and to discuss possible management options.

Patients diagnosed with Lynch syndrome should be offered intensive screening and follow-up according to genetic test results, family history, and personal history of cancer [4,6,60]. Because of the increased lifetime risk of colorectal, endometrial, and other extra-colonic cancers, LS patients and their families require lifelong coordinated multidisciplinary care [55].

Preventive measures (i.e. risk-reducing chemo-preventive agents and risk-reducing surgery) and surveillance protocols such as colonoscopy for early detection of cancers are proven to have a positive impact on patient outcomes and facilitate early diagnosis in individuals with confirmed LS diagnosis [6,42,55].

Genetic counseling and cascade testing of family members at risk of carrying LS-causing variants is highly recommended. Patients should be advised to inform their relatives about the risk of inheriting the identified P/LP variant [42]. In case of a VUS result, family testing could be recommended just for segregation studies to help in variant reclassification, but not for risk estimation or any clinical purposes [43].

Lynch syndrome is typically inherited in an autosomal dominant manner. Each child of an individual diagnosed with LS has a 50% (1/2) risk of inheriting the same P/LP variant [62]. Usually, germline testing for hereditary cancer predisposition of pre-symptomatic individuals is not recommended under 18 years old unless the risk of developing cancer is very high at younger ages and results would impact medical care in childhood [42,62]. Constitutional MMR deficiency (CMMRD) syndrome is one of the exceptions in which testing prior to age 18 is recommended to guide medical care [42].

Prenatal diagnosis or preimplantation genetic testing with selective implantation of unaffected zygotes is technically feasible if a pathogenic variant is known in the family [57,62-64].

CONCLUSIONS

Lynch syndrome is the most common hereditary colorectal cancer syndrome, characterized by high genetic and clinical heterogeneity. Being associated with the early onset of colorectal cancer and other extracolonic malignancies, individuals diagnosed with LS and their families require multidisciplinary care during their entire lifetime. Comprehensive genetic counseling educates patients and at-risk family members about their risks, genetic testing advantages and limitations, and implications of diagnosis. Specific genotype-phenotype correlations were observed and germline molecular testing helps individualize risk-reduction and surveillance strategies according to underlying genetic defect.

Conflicts of interest and sources of funding

The author declares no conflict of interest.

REVIEW

Lynch Syndrome: Approach from the Gastroenterologist's Point of View

Abstract: *Colorectal cancer is one of the main causes of death by cancer in the European Union and in Romania. Lynch Syndrome is an autosomal dominant inherited disease that affects around 3% of all colorectal cancer patients, defined by mutations in the mismatch repair genes (MLH1, MSH2, MSH6, PMS2). Aside from the high risk for colorectal cancer (CRC), they exhibit a high risk for endometrial cancer, ovarian cancer, gastric cancer, pancreatic cancer, brain cancer, small bowel cancer, and sebaceous gland cancer. Diagnosis is often made by the gastroenterologist, usually when he meets a young patient with symptoms suggesting the presence of a colonic tumor and a family history of CRC. The role of the gastroenterologist is to investigate the best practices in order to have an early diagnosis and to prevent interval cancers according to the newest guidelines or other gastrointestinal tract tumors associated with Lynch Syndrome. Registries play an important role in the optimal surveillance of these particular categories of patients and should be put into place in every country. They will allow clinicians to have a better understanding of the disease and a more standardized quality of care for them*.

Keywords: *Lynch Syndrome, colonoscopic surveillance, patient registry*

INTRODUCTION

Colorectal cancer (CRC) represents the second leading cause of death by cancer after lung cancer in the European Union and the second one by frequency of occurrence, making it an important problem of public health in many countries [1]. In Romania, the National Institute of Public Health estimates an incidence rate of 34.6‰$_{00}$ people in 2020, representing 12.7 % of the newly diagnosed malignancies in the oncologist's office. Analyzing past data, we can observe a marked increase in the incidence of new cases from 31.0‰$_{00}$ in 2012 to 34.6‰$_{00}$ in 2020 which medical professionals should take into account [2].

It is estimated that 3-5% of CRC diagnoses are associated with a genetic syndrome, but what is really concerning, is that 35% of CRC have a hereditary predisposition. Lynch Syndrome (LS) is the most common hereditary CRC syndrome and it's the cause of approximately 3 % of all CRC, with an estimate of 1/279 (95% CI, 192–403) of the population carrying a mutation in the mismatch repair genes [3].

LS is an autosomal dominant inherited syndrome genetically diagnosed by a mutation in one of the mismatch repair (MMR) genes (MLH1, MSH2/EPCAM, MSH6, PMS2) [4].

It is characterized by an overall increased risk of CRC, manifested by a predominance of diagnosed right-sided tumors, and a high incidence of metachronous or synchronous tumors [5]. Patients who carry a pathogenic variant of the MMR genes are also at high risk of developing endometrial cancer and some other cancers based on the respective gene defect [6].

Recent guidelines recommend that all newly discovered CRC regardless of age of diagnosis, should undergo testing for mismatch deficiency by immunohistochemistry (IHC) staining for MMR proteins, or microsatellite instability (MSI) by polymerase chain reaction (PCR). If the tumor is either MMR deficient or presents high instability, the patient should automatically be tested for LS. Ideally, genetic diagnosis should happen before chemotherapy is started, considering that, immunotherapy is associated with an improved prognosis in this category of patients compared with the ones having an MMR-proficient tumor. In cases of early-onset CRC, all patients should undergo genetic counseling and be tested for germline genetic mutations regardless of the results of IHC/PCR testing [6].

When faced with a young individual, the patient’s history is very important. The clinician should try to find out all the family history details, making a comprehensive review and ideally also a family pedigree. All causes of death in the family should be noted in order to understand how many of them were caused by the underlying condition and to observe the penetrance of the gene in the respective case [7].

MATERIALS AND METHODS

The studies that we included in this review, are peer-reviewed articles, published in English focused on gastroenterological surveillance in Lynch Syndrome. We used the PubMed database, Springer Link, and Google Scholar and we selected articles published before the 1st of August 2023. We use terms like "Lynch Syndrome" combined with "Colonoscopic surveillance", "Endoscopic Surveillance", "colon cancer", "Pancreatic cancer", and "non-invasive surveillance" and selected relevant articles to the subject. We didn’t include articles that presented small lots of patients and had insufficient data presented. The articles that complied with the search and contained relevant information for our study were included and presented in our study. We also researched the newest guidelines on hereditary colorectal cancer such as the NCNN latest guideline version, the ESMO guidelines but also the Mallorca consensus, and the new Delphi initiative on early-onset colorectal cancer.

RESULTS

As gastroenterologists, we are concerned about the early detection of Lynch-associated tumors and how to best prevent premalignant lesions. New studies discussed the pathways that lead to CRC cancer and what gastroenterologists can do to prevent new malignant lesions. Also, concerning the rarer GI tract cancers associated with Lynch Syndrome, there are new surveillance recommendations published very often and gastroenterologists need to stay up to date in order to offer the best care.

We are going to focus on the best practices in gastrointestinal surveillance, therefore we are going to discuss the early detection of patients, surveillance, and better ways to improve patients’ adherence to a lifetime of screenings.

Detection of patients

When talking about the gastroenterologist's perspective, it is usually concerning a CRC case at diagnosis. The most frequent motives for a doctor's appointment are hematochezia (46%), iron deficiency anemia (13%), and weight loss (10%) [8-11]. Physicians have a tool by applying the Amsterdam II Criteria or the revised Bethesda Guidelines when assessing a patient’s risk for Lynch Syndrome [12-13] (Table 1).

Table 1: Amsterdam II Criteria and Revised Bethesda Guidelines

Amsterdam II criteria
At least three relatives must have cancer associated with LS (colorectal, endometrial, small bowel, ureter, or renal pelvis); all of the following criteria should be present:
One must be a first-degree relative of the other two
At least two successive generations must be affected
At least one relative with cancer associated with LS should be diagnosed before age 50
Familial adenomatous polyposis should be excluded in the CRC cases (if any)
Tumors should be verified whenever possible
Revised Bethesda Guidelines
Tumors from individuals should be tested for MSI in the following situations
CRC diagnosed in a patient who is younger than age 50 years
Presence of synchronous or metachronous colorectal or other LS-related tumors regardless of age
CRC with MSI-high histology diagnosed in a patient who is younger than age 60 years
CRC diagnosed in a patient with one or more first-degree relatives with LS-related cancer, with one of the cancers being diagnosed below age 50
CRC diagnosed in a patient with two or more first or second-degree relationships with LS-related cancer regardless of age

Although throughout the years they proved themselves to be useful tools in the office, the more recently recommended approach is to define the MMR status via IHC staining or MSI using the polymerase chain reaction. Furthermore, the molecular alternative plays an important part in the aftermath of the diagnosis by being a useful indicator of a positive response to the use of immune checkpoint inhibitors [14].

In particular situations, where no tumor tissue is available, like patients with a high suspicion of Lynch Syndrome that don’t have a cancer diagnosis, clinical prediction models have been developed, in order to assess the indication for genetical testing.

The PREMM model ((http://premm.dfci.harvard.edu/), is a useful tool for clinicians, and easy to incorporate in day-to-day work. Recently Harvard developed the new PREMM5 model with an increased chance of predicting whether a patient might carry a germline variant of the genes involved in LS. If the prediction is above the 2.5% limit in the case of the PREMM5 model or more than 5% in older versions, the patient should be referred for genetic testing and further investigations in a geneticist's office [15].

From a gastroenterologist's point of view, the interview is based on onset symptoms, previous lab results, family history, and personal risk factors such as smoking status, gender, and age at diagnosis. Afterward, depending on the situation, whether there is a patient from a Lynch family or a newly identified patient, there are different ways to approach the screening. Patients may be referred to a geneticist in order to receive genetic counseling and to be explained familial risk. A study was conducted in Denmark on the manner in which individuals were informed about their cancer risk. There is a Lynch Syndrome registry implemented since 1991 with continuous improvements, where there is approval from the authorities to send unsolicited letters to patients at risk of familial cancer in order to include them in a surveillance program. The reactions to these letters were studied, and while the results were good, there still was a category of patients upset or angry to be informed of their genetic heritage. Even though the standard recommendation is that family members inform one another, depending on familial situations, and personal preferences, it was decided that the unsolicited letters were helpful in reaching as many members as possible. Potential individuals at risk were invited to genetic counseling and genetic testing in order to assess their further need for surveillance [16].

Colonoscopic surveillance

When talking about colonoscopic surveillance in LS there are several issues to be discussed. First, there are multiple recommendations regarding the screening both concerning the onset age to begin colonoscopic surveillance and also the interval between the procedures. The consensus is that the interval between colonoscopies should not be longer than 3 years as it was demonstrated in some studies that a 3-year window was associated with metachronous cancer [17]. A study conducted by Ahadova et al opened the window to new challenges regarding colonoscopy surveillance. The study presents a new theory that states the fact that carcinogenesis in Lynch Syndrome may occur via more pathways opposite to the previous theory stipulating that it's an accelerated road from adenoma to adenocarcinoma (Table 2). While the classic pathway with the adenoma to adenocarcinoma is still present, they show that adenocarcinomas can develop on macroscopically normal tissue, concluding that a schedule with more frequent colonoscopies won't necessarily prevent the development of new tumors [18]. Even though endoscopists will perform polyp resections when deemed necessary, they can't analyze the normal tissue. In summary, colonoscopy screening with polypectomies performed when necessary did not guarantee that the patient would be risk-free and tumor could appear on apparently normal mucosa. This new information makes colonoscopy surveillance even more important, and respecting the recommended intervals with no more than 2 years interval between exams is crucial in detecting tumors early.

Table 2: Pathways to Carcinoma in Lynch syndrome as stated by Ahadova et al. [18]

Pathway 1	Normal mucosa to Adenoma MMR proficient to MMR deficient Adenoma to Carcinoma
Pathway 2	Normal mucosa to MMR deficient crypt foci to MMR deficient Adenoma to Carcinoma
Pathway 3	Normal mucosa to MMR deficient crypt foci to Carcinoma

Seeing as new information appears every year, new guidelines were published with different recommendations regarding the timing of colonoscopy surveillance, and also the interval between the examinations. Recent data concerning LS patients shows that the on-set age should be different depending on the mutation, with the latest NCCN recommendations stating that in the case of MLH 1 or MSH 2, colonoscopy should start at age 20-25 years or 2-5 years before the earliest CRC diagnosis if it was diagnosed before 25 years of age, with an interval of 1-2 years between examinations. When talking about MSH 6 and PMS2, the guidelines are more relaxed, recommending starting at 30-35 years of age or 2-5 years before the earliest CRC diagnosed before the age of 30 years with an accepted interval of 1-3 years between examinations. If adenocarcinoma is detected in one of the examinations, colonoscopy on the remaining part of the colon should be made every 1-2 years, the same indication going in cases of adenomas that were successfully resected endoscopically. If there are situations when adenomas aren't suitable for endoscopic resection, surgery may be indicated depending on the particular situation [19].

The British Society of Gastroenterology published a new guideline in 2020 on the management of hereditary colorectal cancer making similar recommendations, the difference being in intervals between examinations. It is recommended a 2-year interval between colonoscopies and they also state that screening should end at age 75 years [20]. The ESMO 2019 guidelines are in consensus with the previous ones, making recommendations based on the known gene mutation with a

1-2 years interval between examinations [21]. The ACG guidelines state a slightly different approach to screening with a recommended age at onset between 20-25 years at least every 2 years with a suggestion to perform it annually in confirmed mutation carriers [22] (Table 3).

Table 3: Summary of guideline recommendations for colonoscopic surveillance

Guideline	Age	Interval
NCCN	MLH1/MSH2: 20-25 years or 2-5 years before earliest CRC diagnosis if prior to 25 years of age MSH6/PMS 2: 30-35 years or 2-5 years before earliest CRC diagnosis if prior to 30 years of age	1-2 years 1-3 years
ESMO	MLH1/MSH2: 25 years MSH6/PMS2: 35 years	1-2 years
BSG	MLH1/MSH2: 25 years MSH6/PMS2: 35 years	2 yearly until age 75 years
ACG	Age 20-25 years	1-2 years

One study conducted by the Dutch in 2022 [23] on colonoscopic surveillance of diagnosed LS patients revealed some difficulties encountered on the way regarding adherence to follow-up by the patients. One important difference that was acknowledged was the call for an appointment. Patients who were called by the hospital in order to make the appointment were more likely to undergo colonoscopic surveillance than the ones who were supposed to initiate the call themselves. Another issue at hand was the burden of bowel preparation. Patients were more open to smaller volume preparations than larger ones. Another issue that should be taken into account is the psychological burden. Out of the 197 patients included in the study, 41 answered that they considered quitting the colonoscopic surveillance. Out of them, 6 complained that it reminded them of having LS, 8 said that it did not fit into their schedule, and for 17 of them, the colonoscopy was burdensome. This was mostly found in populations under 40 years of age. The findings suggested that individuals would be more likely to undergo screening colonoscopy when the hospital is the one initiating the discussion in the context of a centralized cancer registry like the one already in place in the Netherlands because it was revealed that many of the patients didn't know which was the right schedule to appoint a new examination. They concluded by recommending new approaches to surveillance in Lynch Syndrome and exploring less invasive methods like noninvasive biomarkers, that would make patients more likely to adhere to a surveillance program.

Another study from the Prospective Lynch Syndrome Database shows interesting results that somehow contradict the before-known recommendations in the matter of interval between examinations. They compared results from different countries that have different examination schedules from yearly in Melbourne to every 3 years in Finland. They concluded that irrespective of the time since the last colonoscopy was performed, the tumor stage distribution was similar. They proposed another theory, one that exists in breast cancer from before, the overdiagnosis [24]. There are cases described in the literature that formulate the hypothesis that the host's immune system could detect neoantigens present on the surface of MSI cells and destroy them. So, performing colonoscopies too often could result in additional unnecessary surgical procedures that could be handled by the immune system [25].

Noninvasive surveillance

Over the last few years, there have been several studies conducted in order to try to find a suitable noninvasive screening method to be implemented in order to avoid performing colonoscopy yearly or every 2 years depending on the country of origin. There have been small studies concerning imaging methods, blood biomarkers, or fecal biomarkers that researchers hoped would help patients avoid the burden of undergoing colonoscopy.

In Australia, Lim et al conducted a small prospective study to compare Magnetic resonance colonography with colonoscopy results, in patients undergoing both procedures on the same day. The MR colonography images were reviewed by two radiologists. They managed to detect three lesions in three patients that were large, 70, 36, and 17 mm respectively, but failed to discover one small-sized adenocarcinoma sized 3 mm, two tubulo-villous adenomas, and one sessile serrated adenoma. They concluded that the examination still had a poor sensitivity in detecting small-sized polyps even though they detected the larger ones. Comparing the methods by patient comfort, even though other studies confirmed that patients admit a lower burden in performing MR colonography than colonoscopy, the burden of bowel preparation remains [26]. There have been other studies made on small sets of patients regarding other noninvasive methods such as stool tests (fecal immunochemical test or microbiota) or blood tests but at the moment none of them have proven to be able to replace screening colonoscopy [27-29].

Upper gastrointestinal (GI) tract surveillance

While most of the gastroenterologist's efforts are driven towards a high quality lower gastrointestinal tract surveillance, considering the high risk of colorectal cancer, gastric cancer, and small bowel cancer are two entities that should be taken into account when talking about Lynch Syndrome surveillance. There is no consensus on onset, interval, or even recommendation to perform upper GI endoscopy up until present. Recent guidelines recommend an individualized approach to gastric cancer screening depending on personal risk; that includes, family members with a diagnosis of gastric cancer, male sex, or increasing age. However, there were cases where risk factors weren't present, which made this a clinician's decision [30]. There is one common point that most guidelines agree upon, universal Helicobacter Pylori testing should be performed, the infection eradicated when discovered, and ulterior testing to confirm the eradication to be done [31]. Recent studies advocate for an early first Upper GI Endoscopy, at 30 years of age or 2-5 years earlier than the first upper GI tract cancer diagnosed in the family, with multiple biopsies taken in order to assess the presence of atrophic gastritis or a presumable Upper GI infection. If symptoms appear, an earlier examination should be performed. While there is no consensus on the best interval between exams, a 2-3 years interval could be a good option if there are no other risk factors to be taken into consideration. Also, the best way to ensure patient adherence to screening is to perform both colonoscopy and upper endoscopy in the same session [32].

Pancreas surveillance

While rarer than the other pathologies mentioned above, pancreatic cancer presents a higher risk in LS patients than in the general population (3.7% vs. 1.5%) [33]. With MLH 1 and MSH 2 mutations being most frequently involved. Another difference between LS patients and the general population is the age at diagnosis, with a mean age of 70 years, in this particular situation it may be diagnosed at a younger age. [34] Unfortunately, there is no standardized screening method for this pathology with the most useful tools at the moment being endoscopic ultrasound and magnetic resonance imaging, both of them being more accurate than a CT scan [35].

DISCUSSION

Lynch Syndrome is a diagnosis with a high impact burden on the patient, that became more common in the past few years with the implementation of standard IHC in all colorectal tumors that are surgically resected. Unfortunately, over the years many patients were missed because of the high cost of the investigations in underdeveloped countries, and physicians made everything possible to try not to miss any patients that may have been at risk for any hereditary cancer syndrome. While there are programs for some genetic mutations to be tested for free, germline mutation for Lynch Syndrome is at the moment available only if patients support the full cost, this situation making many patients refuse it for the moment being. Romania is a country undergoing medical developments with new projects to create national registries set into motion. Seeing as in other countries registries helped medical professionals follow certain categories of patients and improve their outcome, all countries are trying to achieve the same results.

The gastroenterologist is an important part of the diagnostic equation in this syndrome, alongside the gynecologist is usually the first medical professional that identify potential LS patients. That being considered, it is very important that all gastroenterologists should know the clinical features of LS in order to correctly identify patients at risk and send them to a geneticist. Colonoscopic surveillance, but also upper GI surveillance should not be performed at any center but only in the highly specialized ones by trained endoscopists with experience in screening colonoscopies for particular populations. A high-quality colonoscopy should be performed, ideally with the help of chromoendoscopy and of high definition white light endoscopy. Trained specialists know how to assess lesions properly when discovered and to decide which one should be excised endoscopically and which should go to surgery. It is a field in continuous development where new information appears every year. The existence of patient registries is very important and should be made a priority in every country, to allow patients to have high-quality surveillance in specialized centers and receive the best care possible to improve their lifetime expectancy and quality of life.

CONCLUSIONS

Surveillance of Lynch Syndrome patients is very challenging, with new information emerging every day, making the physician's job even more interesting. That is why it is very important to have more gastroenterologists specialized in the pathology associated with LS to ensure an appropriate standard of care for this category of patients.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Acknowledgments

A special thank you goes to Oana Cristina Voinea, the founder of the Romanian Society for Lynch Syndrome who fights every day to improve the standard of care for the patients and offer them a chance to a normal life and inspired this article.

Abstract: *Background: A germline mutation of the MisMatch Repairgene that causes a malfunctioning DNA system is the defining feature of the hereditary illness known as Lynch syndrome. This review will discuss the endocrine aspects of LS and highlight current advancements in the area. Methods: We searched the available literature of the last 10 years for terms such as endocrine tumors and LS. Our goal is to provide a summary of the most recent information available on the endocrine perspective in Lynch syndrome. Results: The hormonal chemoprevention methods cited are the use of combined oral contraceptives, the use of progestogen-releasing intrauterine devices, and the use of progesterone-only drugs. In addition, after surgical exclusion of the uterus and ovaries, a method frequently adopted for LS patients, it is necessary to start hormonal menopausal therapy, taking into account certain age-specific features. In addition, numerous LS-associated endocrine tumor types have been described. Conclusions: Many hormonal variants are available that are useful in the chemoprevention involved in the treatment of LS. Menopausal hormone therapy is imperative for LS patients who need it. Clinicians need to be aware of the possible association of certain types of aggressive endocrine cancers associated with LS.*

Keywords: *Lynch syndrome, endocrine tumors, menopausal hormone therapy*

INTRODUCTION

The most prevalent hereditary colorectal cancers are those caused by Lynch syndrome (LS), also known as hereditary non-polyposis colon cancer. This autosomal-dominant disorder causes colorectal cancers to develop on average 10 years sooner than sporadic colorectal neoplasia [1].

Lynch syndrome is caused by inherited mutations or pathogenic variations of the genes of the MisMatch Repair (MMR) system involved in the DNA repair system: in the mutL homolog 1 (MLH1), mutS homolog 2 (MSH2), mutS homolog 6 (MSH6) and PMS1 homolog 2 (PMS2) genes. In addition, epithelial cell adhesion molecule (EpCAM) deletions of the 3' end may result in the epigenetic silencing or inactivation of MSH2. More rarely, germline hypermethylation of the MLH1 promoter area might result in hereditary inactivation of the MMR system. Failure of the MMR system causes a loss of expression of one or two MMR proteins with a consecutive increase in the number of MMR proteins and leads to an increase in errors during DNA replication. In addition, tumors that develop in the spectrum of LS also exhibit microsatellite instability and loss of expression of one or two MMR proteins [1,2]. The future of LS screening may involve using next-generation sequencing to check for microsatellite instability and find mutations in the MMR genes [3].

This syndrome is associated with a significantly increased risk of colorectal cancers along with carcinomas of the endometrium, upper urinary tract (mainly renal pelvis and ureter), ovary and small intestine, stomach, sebaceous tumors (adenomas and sebaceous neoplasms, keratoacanthomas), brain tumors (gliomas), pancreatic and bile duct tumors [4]. Furthermore, there have been observed genotype-phenotype connections, such as an increased incidence of extracolonic tumors or multiple malignancies in individuals with MSH2 mutations [3].

From the endocrinologist's perspective, patients with Lynch syndrome may require clinical and therapeutic management of surgically induced primary menopause with all its associated risks, as well as screening and possible treatment of other associated endocrine cancers.

Additionally, it's critical to accurately and promptly diagnose LS using medical genetic techniques because it affects both the patient and their family in terms of the moment and type of surgery, long-term monitoring, and screening tests for various tumor types.

MATERIAL AND METHODS

We searched PubMed for English and French full-length publications, aiming to compile a narrative mini-review, through a search starting from the terms ''lynch syndrome'', and associated "endocrine tumors" searching for "thyroid tumors", "adrenal tumors", "pituitary tumors", "testicular tumors". We used as inclusion criteria original publications, regardless of the level of statistical significance, full-length articles, and the French and English language, for the last 10 years. Exclusion criteria were non-English papers, non-French articles, and non-endocrine disorders associated with LS, usually not referred to the endocrinologist. We followed the main endocrine tumors associated with LS, as well as the importance of hormonal treatment in women with LS. Searching for the term "thyroid tumors" associated with Lynch syndrome, we found 17 publications, including 4 case reports and 3 cohort studies. In addition, searching for the term "adrenal tumors" associated with Lynch syndrome in the last years, we found 21 articles, 5 of which were case reports. Similarly, when searching for the term pituitary tumors, the search resulted in 6 publications of which 3 case reports. Searching for the term "testicular tumors" associated with Lynch syndrome in the last 5 years, we found 7 articles, 2 of which were case reports. In addition, searching for other endocrine tumors described with Lynch syndrome we found a case report with a parathyroid carcinoma and one clinical case of thymic carcinoma.

RESULTS

From the endocrinologist's perspective, of interest are how to optimally treat and monitor premature menopause associated with LS treatment and the clinical approach to endocrine tumors developed within this syndrome, especially thyroid, adrenal, but also testicular, pituitary, parathyroid, and thymic tumors.

Premature menopause may develop in patients with LS either induced by prophylactic or curative surgery or secondary to chemo and radiotherapy procedures that may be part of the therapy. The impact on patients, often young women under the age of 45 years, has numerous implications both endocrinologically, on fertility, as well as metabolically, cardiovascular, cognitive, bone, and not least psychologically.

The clinical management of premature menopause is carried out as a team with the gynecologist who is responsible for the diagnosis of ovarian and endometrial pathology associated with the LS. Our article will not focus on the diagnosis and treatment of gynecological pathology, but only on the hormonal and non-hormonal treatment of endocrine consequences, i.e. the treatment of premature menopause and the possible hormonal approach to LS patients. After scanning the specialized literature we will systematize the information found according to endocrine disorders.

Thus, we will first discuss the endocrine consequences of the clinical management of ovarian or endometrial cancer and the possible hormonal and non-hormonal treatments of premature menopause associated with LS. Then, we will detail other endocrine tumor types associated with this syndrome.

1. Ovarian and endometrial cancer

The foremost conditions associated with gynecologic cancers include LS and hereditary breast and ovarian cancer. About 2-3% of all endometrial cancers are considered to be associated with LS [5].

LS genes vary in clinical penetrance, with a lifetime risk of developing endometrial cancer of up to 60% and a risk of up to 24% for developing ovarian cancer, especially in the carriers of MSH2 [6]. On the other hand, PMS2 carriers, in particular, have a lower lifetime risk of cancer than other LS genes[7].

In terms of clinical approaches, we will discuss in the following both general methods of lifestyle optimization and methods of chemoprevention, as well as surgical options to reduce the risk of gynecological cancer.

Regarding lifestyle suggestions, patient education includes methods to lower cancer risk factors generally, such as quitting smoking, getting regular physical exercise (150-300 minutes of moderate-intensity weekly exercise), maintaining a healthy weight, eating a healthy diet (rich in vegetables and fruits and less red meat), limiting or eliminating alcohol, guarding against sexually transmitted diseases, avoiding sun exposure, and getting adequate cancer screenings [8]. However, no particular research has been done on how this broad advice may affect LS patients.

Chemoprevention

The first drug therapy used as chemoprevention in LS is the use of aspirin, as it can reduce the incidence of colorectal cancer. Studies indicate starting with a dose of 325 mg of aspirin per day, with consecutive increases to a dose of 650 mg per day after several months of treatment if aspirin is tolerated without side effects. In patients who have side effects following aspirin treatment or those with a personal and family history suggesting a lower risk of cancer, a lower dose of aspirin may be used [9]. In addition, taking aspirin diminishes the risk of developing all neoplasia in LS gene carriers. Aspirin appears to reduce the risk of endometrial neoplasia in obese women with LS compared to non-obese women [10].

In addition, in terms of hormonal chemoprevention, combined oral contraceptive pills (COC), progestin-only pills, or progesterone-containing intrauterine devices (IUD), are an alternative form of risk-reduction for those with LS, before to completion of the childbearing period and prior to risk-reducing surgery.

Moreover, data on the prevention of endometrial cancer with hormonal therapies in women with LS are limited and most of the evidence is extrapolated from studies in the general population.

Regarding COC, their use is known to decrease the lifetime risk of endometrial and ovarian neoplasia by 50%. Importantly, the protective effects of using COC become stronger the longer the use [11]. A retrospective cohort study showed that patients with LS who received hormonal contraceptives for more than 1 year had a reduced risk of endometrial cancer [12]. However, COC use raises the risk of breast cancer by up to 38% in the general population, if used for more than 10 years [13].

In a retrospective analysis, women with LS who used hormonal contraception for at least a year — in the form of a COC progestin-only pill, or an implant, had a 61% lower risk of developing endometrial cancer [14].

Table 1: Non-surgical prevention methods in LS *(adapted after Lynch syndrome for the gynecologist, Neil AJ Ryan et al)*

	Combined oral contraceptives	**Menopausal hormone therapy**	**Levonogestrel Intrauterine Device**	**Depo Provera Medroxyprogester one Acetate**	**Lifestyle measures***	**Aspirin**
Timing	Before surgical prophylactic surgery, 2 years after menarche	After surgical excision until the normal age of menopause	Method of chemoprevention, 2 years after menarche	Method of chemoprevention, over 18 years old	Any time	Method of chemoprevention, From 18 years old
Mechanism of action	Prevention of ovulation decreased endometrial proliferation	Anti-inflammatory impact decreased endometrial proliferation	Decreased endometrial proliferation	Decreased endometrial proliferation	Decrease of cancer risk factors	Not fully described
Contraindications	Hypertension, breast cancer, ischemic heart disease, migraines with auras, endometrial cancer, cirrhosis, hepatocellular adenoma, malignant hepatoma, history of venous thromboembolism	History of estrogen-dependent or breast cancer, active arterial thromboembolic disease, undiagnosed vaginal bleeding, thrombophilia disorder, history of venous thromboembolism	Sexually transmitted infection, congenital uterine abnormality, pelvic inflammatory disease, Confirmed or suspicion of uterine or cervical malignancy, abnormal uterine bleeding	Undiagnosed vaginal bleeding, active thrombophlebitis or past history of thromboembolic disorders or cerebral vascular disease, gallbladder disease, history of diabetes, coronary artery disease, or a current tobacco smoker age ≥ 35	Those who have health issues that would prevent them from doing too much physical activity	Severe heart failure, hemophilia, peptic ulcer disease, active abuse of alcohol
Adverse effects	Breakthrough bleeding, nausea, headaches, abdominal cramping, breast tenderness, decreased libido	Dysuria, skin reactions, mood alterations	Headache, acne, breast tenderness, weight gain, cramps or pain during menstruation, depression	Headache, acne, hirsutism, weight gain, depression	-	Dyspepsia, digestive haemorrhage

** reduce weight, increase physical exercise, healthy diet, smoking cessation*

Moreover, the use of depo-medroxyprogesterone acetate (depo MPA) or COC was specifically evaluated in LS patients, showing evidence of a marked decrease in endometrial proliferation [15]. However further investigation of these hormonal agents in this high-risk population is needed.

The levonorgestrel intrauterine device (IUD) releases progestin directly into the endometrium, attenuating the stimulatory effects of estrogen and it is frequently used to treat endometrial intraepithelial neoplasia and low-grade endometrial cancers. Studies have shown that all levonorgestrel IUD users have a reduced risk of endometrial and ovarian cancer in the general population, without an increase in the risk of breast cancer and this decreased risk persists for 5 years following discontinuation [14,16]. Unfortunately, POET, a randomized trial that aimed to ascertain whether the levonorgestrel IUD was effective at preventing endometrial neoplasia in women with LS, was prematurely stopped due to a lack of enrollment [8].

Thus, data on general lifestyle measures and chemoprevention methods used in LS have been systematized in Table 1.

Risk-reducing surgery

Regarding the option of preventive surgery, the Manchester Consensus Group recommends that total hysterectomy with bilateral salpingo-oophorectomy should be offered to patients no earlier than 35-40 years after cessation of the childbearing period in carriers of proven pathogenic MLH1, MSH2, and MSH6 genes. Furthermore, for pathogenic PMS2 heterozygotes, the usefulness of preventive surgery is not proven. It is also recommended to consider a woman's personal risk in order to provide individualized advice on the optimal timing of the surgical procedure [2].

Moreover, women with LS, especially when they are premenopausal and/or women over 40 who have chosen not to undergo total hysterectomy with bilateral salpingo-oophorectomy and who opt for periodic surveillance should have an annual follow-up with a gynecological specialist with knowledge of the syndrome [8]. In addition, a study reported that the risk is higher in the case of MSH6 gene mutation compared to MLH1 and MSH2 gene mutations [17].

The largest study comparing patients with LS concluded that prophylactic hysterectomy with bilateral salpingo-oophorectomy is an effective strategy for preventing endometrial and ovarian cancer in women with LS [18].

Currently, there is no recommended screening strategy for gynecologic cancers with demonstrated efficacy in the setting of LS. The annual association of the clinical examination and the endovaginal ultrasound is proposed [8]. In addition, some studies indicate the performance of the annual endometrial biopsy, is correlated with the monitoring of the CA-125 marker levels [2]. In any case, women should be warned that the appearance of metrorrhagia should lead to a specialist consultation as soon as possible and a diagnostic examination. Most endometrial cancers are diagnosed at an early stage, with a favorable prognosis similar to sporadic ones. In particular, the distribution of uterine tumor localization seems to be different in patients with LS [19]. It is worth noting that while in the case of endometrial cancer patients without LS, the tumor develops in the uterine body, for patients with this syndrome there is a greater risk of tumors of the lower segment of the uterus, which can be misdiagnosed as cervical adenocarcinomas [5].

These risk-reducing operations might lead to early menopause, infertility, and surgical complications, which would have a major negative impact on general health and quality of life. Patients need to be informed about the advantages and disadvantages of this gynecological surgery in terms of the morbidity of the operation and especially the medium and long-term consequences of surgically induced menopause.

The surgical complications rate varies by 1.6-9%, including events such as bowel and urinary tract injuries, bleeding, and infections [18]. Patients should be informed about the symptoms of surgically induced premature menopause, including vasomotor symptoms, sleep disturbances, decreased libido, symptoms of vaginal atrophy but also long-term systemic implications such as osteoporosis, the risk of cerebrovascular disease, cardiovascular disease, and accelerated neurodegenerative aging [20] .

However, studies continue to advise risk-reducing surgery for LS patients who have finished the childbearing period rather than cancer surveillance and chemoprevention [8].

Impact on Fertility

In addition, patients with LS should be referred shortly after diagnosis to clinicians with expertise in female reproductive endocrinology and gynecologic oncology for counseling on gynecologic cancer surveillance. In addition, patients need counseling on fertility, fertility preservation options, use of assisted human reproduction techniques (ART) as well as other options regarding the desire to have children, such as adoption or surrogacy. Additionally, in the case of ART, preimplantation genetic testing to prevent implantation of an affected embryo or prenatal diagnosis to determine if the fetus is affected is recommended in LS [21].

Consideration of fertility preservation options is an important component of the management of patients with LS. Early referral of patients known to carry pathogenic gene variants to reproductive endocrinology specialists at age 20-30 is recommended so that they can be informed about their own follicular reserve, fertility preservation, and potential for preimplantation genetic testing. This allows early assessment of baseline ovarian reserve and enables interested women to achieve spontaneous pregnancies at younger ages or to access ART when the methods are most likely to be successful. Through ART, patients have the option of cryopreserving and storing oocytes, embryos, or both [22].

Generally, during a cycle of controlled ovarian hyperstimulation, the ovaries are stimulated with exogenous gonadotropins, followed by ultrasound-guided transvaginal needle aspiration of the oocytes. However, there is some concern in patients carrying gene mutations about the effect of high levels of oestradiol generated during ovarian hyperstimulation on the risk of developing gynecological cancer. Fortunately, data from the literature indicate that the use of fertility drugs does not appear to increase the risk of breast cancer in patients with prior breast cancer or BRCA gene mutation carriers, having no impact on survival rates, at least in the short term. However, in these patients, it is recommended to minimize the increase in oestradiol levels by using an aromatase inhibitor (letrozole) in addition to using the gonadotropin stimulation protocol, which leads to lower, physiologically similar oestradiol levels. In the case of a patient who has cryopreserved oocytes or embryos prior to bilateral adnexectomy, pregnancy can still be achieved by hormonal preparation of the preimplantation uterus and embryo transfer. However, if a woman does not have her own oocytes or embryos available, she may consider using donor oocytes, or donor embryos, or turning to adoption [21].

For a woman of reproductive age who has opted for total hysterectomy either for treatment or as a preventive method to reduce the risk of cancer, who wants a child from her own gametes, ART can be used to obtain her own oocytes, which are then used in a gestational carrier. Medical, legal, and psychological counseling should be considered for both the prospective parents and the gestational carrier. Uterine transplantation is also a procedure that has recently resulted in live births, but its role in preserving fertility in patients at high risk of hereditary gynecological cancer has not yet been determined [5].

For patients in whom testing reveals a low ovarian reserve, we would recommend that pregnancy is unlikely and that options for becoming parents include adoption or the use of donor eggs or embryos.

Concerns regarding the long-term safety of fertility drugs and procedures have been raised due to the usage of reproductive treatments that may lead to repeated ovulation and changes in endogenous hormone levels, especially in hereditary gynecologic cancers, such as LS [23]. Although certain clinical research has revealed a connection between fertility medications and the risk of cancer, it can be challenging to evaluate the findings of these investigations. Based on the available data, the risk of invasive ovarian cancer is not significantly increased after the use of fertility drugs in infertile women [21].

Offering choices for prenatal testing, including pre-implantation genetic diagnosis, and carrier testing to persons of reproductive age is crucial. About 50% of a parent's kids can be affected by the autosomal dominant condition LS, which can be passed on from either parent. Couples should also be informed of the risks and potential outcomes of conceiving a child with constitutional MMR deficiency syndrome if both spouses have pathogenic mutations in the same MMR gene. To find out if the spouse carries pathogenic mutations in the same MMR gene, carrier testing might be made available. This is especially important since MSH6 and PMS2 mutations are widespread in the community and may not be strongly correlated with a substantial family history of cancer, even though they may be linked to a more moderate penetrance phenotype [24].

Menopausal hormone treatment

In terms of treatment decisions, endocrinologists generally form a clinical management team with gynecologists.

Menopausal hormone treatment (MHT), is a general term that refers to both unopposed estrogen usage for women who have had hysterectomies and also the combination estrogen-progestin therapy for women who still have their uteruses intact but require a progestin treatment to avoid estrogen-associated endometrial hyperplasia. MHT is sometimes referred to as "hormone therapy", although in the past it was known as "hormone replacement therapy". MHT can prevent and relieve most of the symptoms associated with surgically induced premature menopause. Non-hormonal treatment strategies are also available for women who have contraindications to MHT for the treatment of vasomotor symptoms and for the alleviation of genitourinary syndrome symptoms, including selective serotonin reuptake inhibitors (SSRIs), alpha 2 adrenergic agonists, and alternative medicine approaches such as the use of black cohosh, soy, flaxseed, vitamin E , yoga exercise and meditation [25].

Decisions about whether or not to use MHT should be individualized, taking into account the potential risk-benefit balance, severity of estrogen deprivation symptoms, personal and family history of cancer, and therapeutic goals [25].

In addition, recommendations in the Endocrine Society's 2015 Clinical Practice Guidelines suggest calculating cardiovascular and breast cancer risks before initiating MHT for any patient [26].

Although it has not been specifically researched in a Lynch population, MHT is generally regarded as safe for the treatment of surgical menopause after prophylactic surgery in premenopausal women. Women also benefit from requiring only estrogen replacement therapy, which is also advised after hysterectomy for endometrial cancer risk reduction in LS. In particular, for women with LS who undergo premenopausal surgery, experts advise considering MHT [8,14]. It's interesting to note that there is evidence that MHT protects against the development of colorectal cancer in the general population, which may be beneficial for women with LS, regardless of the type of oral or cutaneous MHT product, although further studies in this specific population would be needed [27]. Furthermore, researchers stated that MHT is advantageous in survivors of colorectal cancer [23].

Thus, in the case of young LS patients who opt for preventive surgery with full knowledge of the consequences, MHT should be started as soon as possible. In the absence of contraindications, MHT is recommended for clinical management of relief symptoms as well as for bone, cardiac, and cerebral health.

In addition, the guidelines recommend initiating MHT immediately after the diagnosis of premature menopause and prescribing higher doses of estrogens to mimic endogenous estrogen levels in younger, menstruating women compared to women who are menopausal at a normal age in their 50s. In addition, it states that MHT should be continued until the age of natural menopause, at which point the appropriateness of extending MHT should be reassessed [20].

In the absence of contraindications, MHT is recommended for relief of clinical symptoms as well as for cardiac, cerebral, and bone health and benefits [23].

It is recommended to start treatment with transdermal oestradiol which is biochemically similar to endogenous oestradiol. In addition, the use of the transdermal route avoids hepatic metabolism, with less metabolic impact. Alternatively, oral estrogens or a vaginal ring through which systemic doses of estrogen are administered can be used. Depending on the patient's preferences and whether she has a uterus, endometrial protection can be provided in several ways. If the patient wishes to become pregnant, it is recommended to use micronized progesterone rather than a synthetic progestogen for 12 to 14 days per month[28]. The absence of bleeding at the end of therapy or near the end of cyclic progestin therapy is an indication of a pregnancy test. If conception has occurred, MHT should be discontinued. For women without a uterus, established evidence does not justify the concomitant use of progesterone because endometrial protection is not necessary [5,20,26].

Women who underwent bilateral salpingo-oophorectomy before the age of 45 and were treated with estrogens until at least 45 years of age had a decreased risk of osteoporosis [29].

However, following basic guidelines for preserving bone health, bone mineral density should be assessed as soon as the start of premature menopause [20].

In addition, in a study of the Women's Health Initiative, women assigned to receive estrogen therapy who underwent bilateral salpingo-oophorectomy before the age of 45 years had a reduction in long-term all-cause mortality [30].

Guidelines for the prevention of bone and cardiovascular disease also recommend the adoption of general healthy lifestyle measures: weight regulation, exercise, restful sleep, smoking cessation, moderation of alcohol consumption, adequate calcium and vitamin D intake, and management of blood pressure, lipid and glucose levels [20].

Thus, it should be noted that the use of estrogen comes with a number of warnings and precautions, including a higher risk of gallbladder disease; if severe hypercalcemia, eyesight loss, or cholestatic jaundice develops, estrogen usage should be stopped. In addition, women getting thyroid replacement treatment should have their thyroid function checked regularly [5].

2. Endocrine tumors associated with LS

Adrenocortical carcinoma

Adrenocortical carcinoma (ACC) is a rare, aggressive cancer that starts in the adrenal gland's outer layer. ACC was associated with LS, even though it is known that it belongs to the Li Fraumeni syndrome tumor spectrum due to a TP53 mutation [31]. In a recent study, 3 patients out of a total of 634 patients carrying a germline mutation in the MSH2 gene were diagnosed with non-secretory ACC, corresponding to an incidence of 0.47% of all patients and 1.7% of all patients with MSH2 mutation, similar to other less common neoplasms considered to be part of the LS spectrum.

The association of ACC and LS was initially described in 2013 in a study that reported that 3.2% of LS patients had ACC [32]. Moreover, in 2016, the first case of familial ACC in association with an MSH2 pathogenic mutation was reported [33].

However, at this time, there is no need to advocate routine ACC screening for individuals with LS; nevertheless, physicians should have ACC on their minds for LS patients who have adrenal masses or other clinical signs of overactive adrenal glands [34].

Thyroid cancer

The first case described in the literature was an LS patient with a germline MSH2 mutation who developed undifferentiated thyroid cancer as an index case. Another case described was a thyroid cancer case in a patient with LS with anaplastic thyroid cancer as index cancer.

Another case reported was a synchronous association of papillary thyroid carcinoma and metachronous breast cancer with progression to metastasis [35]. In addition, a cohort study of 383 participants showed co-occurrence of familial non-medullary thyroid cancer (FNMTC) with LS, showing a heterozygous MSH2 gene modification exclusively in the FNMTC-LS family. FNMTC was more prevalent in females in 68.3% and was characterized by a mean tumor size of 1 cm, having multifocal growth in 44% of cases and extrathyroidal extension in 11.3% of cases [36].

Pituitary tumors

Additionally, a patient with LS who had an MSH2 mutation and had significant clinical Cushing disease was documented. He had corticotroph pituitary carcinoma. Furthermore, an invasive nonsecreting macroadenoma and a microprolactinoma, two clinically significant pituitary tumors, were described in a cohort study of 910 patients with LS from Sweden [37].

Testicular tumors

Moreover, a histopathological case report also described a clinical case that led to the broadening of the clinical tumor spectrum of LS by a clinical case of testicular seminoma associated with loss of MSH2 function [38]. Although there have been reports of MSI and MMR deficiency in testicular cancers that are resistant to chemotherapy and have a shorter time to recurrence, testicular cancer is not considered a member of the LS tumor spectrum. Despite the conflicting data reports, it is probably still desirable to investigate individuals with chemoresistant or recurrent testicular cancer for a potential link with LS [34].

Parathyroid carcinoma

Even while parathyroid carcinoma is extremely uncommon — it only makes up 0.005% of all malignancies — and isn't typically seen of being a member of the group of cancers that are connected with LS, one case report was recorded. Thus, a patient with severe hypercalcemia resistant to zoledronic acid accompanied by hyperparathyroidism and MSH2 and MSH6 deficiency was noted, demasking metastatic parathyroid carcinoma [39].

Thymoma and thymic cancer

Thymoma in LS patients has also been documented, as well as a unique occurrence of thymic cancer in a patient who carries the MLH1 heterozygous mutation [40].

CONCLUSIONS

Endometrial and ovarian cancer are more common in people with LS. Hormonal therapies, including combined oral contraceptive pills, only progestin treatment, or progesterone-containing intrauterine devices, are an alternative form of chemoprevention for those with LS. The risk of passing on hereditary pathogenic gene variants to their offspring, future fertility options, and the potential use of hormone replacement therapy after risk-reducing surgery should all be discussed with women who have LS.

Bone mineral density should be measured as early as the onset of premature menopause, following general recommendations for maintaining bone health. In addition, cardiovascular risks should be assessed and managed, and the patient should be encouraged to follow healthy lifestyle measures.

Further studies are needed on the role played by drugs involved in the chemoprevention of endometrial and ovarian cancers, to decide the appropriate time for prophylactic surgery and the ideal time for fertility, in order to enable physicians to prevent and identify Lynch-associated cancers earlier, thus reducing morbidity and mortality caused by this syndrome.

Other endocrine tumors have been described such as adrenal carcinoma, thyroid cancer, aggressive pituitary tumors, parathyroid, testicular, and thymic tumors.

Abstract: *Lynch syndrome, also known as hereditary non-polyposis cancer syndrome, represents the most common autosomal dominant genetic predisposition for the early onset development of several malignancies. Nearly three decades ago, the discovery of microsatellite instability, a distinctive feature of pathogenic variants within genes encoding mismatch repair proteins, marked a significant leap forward in understanding cancer biology and the underlying spectrum of cancers triggered by these mutations – typical of Lynch syndrome. In recent years, a new treatment paradigm, using immune checkpoint inhibitors, as well as preventive measures has drastically improved the survival rates. Identifying individuals with an inherent predisposition to cancer, through diagnostic protocols followed by personalized screening and treatment algorithms, holds the potential to mitigate premature cancer-related fatalities as well as preventable mortality. It is estimated that only a limited number of patients have been diagnosed, underscoring the importance of implementing specific screening programs for early detection of malignancies to which these patients are susceptible. This article aims to underline the importance of a national protocol tailored to guide a Western-inspired practice for Lynch syndrome patient management, the main aim of the Romanian Society for Lynch Syndrome, by providing an overview of similar initiatives throughout the world.*

Keywords: *Lynch syndrome, national registry; international consortium*

INTRODUCTION

In this article, we provide an overview of the key historical milestones in the management of Lynch's syndrome. Our review spans global geography, with the aim of highlighting the imperative for a national Romanian registry of Lynch syndrome, alongside tailored management initiatives. Additionally, we aim to identify the most straightforward and expeditious approaches to implementing global guidelines within the Romanian healthcare system.

Hereditary non-polyposis cancer syndrome was first studied by American pathologist A. S. Warthin, in 1895, in the family of a seamstress, with a generous background of cancers. [1] Warthin didn't manage to convince the scientific community that cancer prevalence within this family was not a coincidence, despite having published the oncological background of the seamstress's German family, known as "Family G", that had a history of very specific cancers, mostly digestive and gynecological. As such, the topic was left dormant for years. [2] In 1971, Henry T. Lynch, MD revisited "Family G", gathering data on 929 descendants. The clear presence of an autosomal dominant cancer predisposition pattern prompted the initiation of molecular investigations. Subsequent analysis revealed microsatellite instability as a distinguishing feature of these tumors. The underlying reason was attributed to a deficiency in the Mismatch Repair (MMR) system, with the responsible genes duly identified, reporting on the specific mutation in the MSH2 gene for the "G Family". [3,4] Henry T. Lynch formulated the fundamental principles of oncogenetic syndromes (heritable cancers): an early age of cancer onset, a distinct pattern of primary cancers, and a Mendelian inheritance model observed in families worldwide. He emphasized that identifying the genetic predisposition to develop cancers holds both prognostic and therapeutic implications. [4]

The acknowledgment of a genetic predisposition that substantially increases the risk of cancer, predictably affecting specific organs, has prompted global efforts to identify susceptible patients; this is driven by an understanding that closely monitoring organs prone to such risks – the digestive tract, reproductive and urinary systems, as well as the skin – represents the optimal approach for bolstering survival rates. To aid in the identification of potential patients, the Amsterdam Criteria were introduced in 1990. [4]. Understanding the biology of deficient MMR tumors, their accelerated growth rate [5], and the tumor immunogenicity carrying therapeutic implications, through the widespread employment of immunotherapy [6] or prophylactic measures like vaccines which are already in advanced stages of clinical studies [7,8] form the foundation for early detection and standardized management of these patients.

MATERIAL AND METHODS

We conducted a comprehensive search on PubMed for English full-length publications with the intention of creating a concise narrative review. Our query used the keyword “Lynch syndrome management”, aiming to encompass information from several continents. Our inclusion criteria featured original publications from the past 10 years, provided they were in full-length format and written in the English language. We excluded non-English papers, articles focusing solely on isolated tumors associated with Lynch syndrome, and those lacking a systemic impact. Throughout our research, we adhered to prominent international guidelines and consensus related to the diagnosis, screening, and treatment of Lynch syndrome. We found 872 relevant publications for the search term “Lynch syndrome management”. Furthermore, when exploring the intersection of "consortium" and Lynch syndrome over the recent years, we identified 84 articles. Similarly, our query for “Lynch syndrome management guidelines” yielded a total of 182 relevant publications, narrowed down to 95 when focusing on the last 5 years. When we searched for “Henry T Lynch” as an author, we found 294 publications, from which 82 regarded Lynch syndrome pathogenesis, manifestations spectrum, or management options.

RESULTS

The prodigious scientific activity of Henry Lynch is explicitly synthetized in almost 100 articles in which he aimed to find an optimal methodology for diagnosis, being aware that the new paradigm in oncology will impact in a significant way the survival of these patients. Describing the biological particularities of tumors attributed to Lynch Syndrome, he was a visionary regarding tailored screening programs, novel therapeutic options, and chemoprevention. Several international consortiums were coagulated aiming to find families and to study their particularities.

The Birth of Diagnostic Criteria

The Netherlands took the first step by identifying 22 families with a genetic predisposition to develop cancers. In 1983, a registry was set up in The Netherlands, overseen by a committee comprising multiple hospitals. The foundation’s objectives include enhancing monitoring within families with predispositions to hereditary tumors, ensuring consistent periodic assessment, and providing guidance to both general practitioners and medical specialists on screening approaches. [9] Dutch researcher Hans Vasen, MD was one of the leading minds behind the inception of the “International Collaborative Group on Hereditary Non-Polyposis Colorectal Cancer” (ICG-HNCPCC). This initiative was conceived during a CRC conference in Jerusalem in 1989 and held its inaugural gathering in Amsterdam in 1990. It was during this meeting that Vasen introduced the initial Amsterdam Criteria, also known as the 3 2 1 rule. Following this, the ICG-HNPCC would meet every year until 2001. [4]

The inception of a prominent new organization, InSiGHT (International Society for Gastrointestinal Hereditary Tumors), stemmed from the merger of ICG-HNPCC with the Leeds Castle Polyposis Group (LCPG), carried out over several meetings, in 1999 in Lorne, Australia, in 2000 in Tiberias, Israel, and in 2001 in Venice, Italy, respectively. [10,11]

These guidelines played a crucial role in pinpointing familial groups that ultimately unveiled the connection between the HNPCC syndrome and inherited mismatch repair gene mutations (MMR) [12-14]. However, the guidelines do not account for extracolonic cancers or apply to smaller family groups.

Both sets of criteria were later revised, as their original variants presented insufficient diagnostic sensibilities and specificity, leading to the omission of numerous patients with Lynch syndrome.

The Revised Amsterdam Criteria (Amsterdam II)

The identification of at least three relatives with HNPCC-associated cancer (cancer of the colon or rectum, endometrium, small bowel, ureter, or renal pelvis) and:
I. One should be a first-degree relative to the other two;
II. At least two successive generations should be affected;

III. At least one should be diagnosed before age 50;
IV. Familial adenomatous polyposis should be excluded;
V. Tumors should be verified by pathological examination. [14]

The Revised Bethesda Guidelines
I. Individual with CRC diagnosed by age 50;
II. Individual with synchronous or metachronous CRC or other HNPCC-associated tumors, regardless of age;
III. Individual with CRC and MSI-H histology diagnosed by age 60;
IV. Individual with CRC and more than one FDR with an HNPCC-associated tumor, with one cancer diagnosed by age 50;
V. Individuals with CRC and more than two FDRs or SDRs with an HNPCC-associated tumor, regardless of age. [15,16]

In November 1996, the Early Detection Branch of the U.S. National Cancer Institute held a global workshop titled "The Intersection of Pathology and Genetics in the Hereditary Nonpolyposis Colorectal Cancer (HNPCC) Syndrome", in Bethesda, Maryland. The workshop sought to elucidate the genetic influence on HNPCC pathology, discussing topics like genomic instability, multistep carcinogenesis, mismatch repair gene involvement, HNPCC histopathology, potential molecular correlations, cell proliferation markers, their relevance to early diagnosis and prognosis, and potential clinicopathologic criteria for identifying more HNPCC patients. [17]

The diagnostic landscape of Lynch syndrome has seen significant advancements through the formulation of the Amsterdam and Bethesda criteria (and their revised versions). As we delve into this realm, it becomes relevant to also consider the contributions of the Ontario Familial Colon Cancer Registry (OFCCR). The organization is an innovative database gathering family histories, epidemiological records, blood samples, and tumor specimens from a relevant sample of colorectal cancer patients and their families. Achieving substantial response rates in genetic family investigations is particularly difficult, due to time demands and confidentiality concerns. Notably, the inaugural year of the registry saw a 61% response rate, with 1,395 probands taking part. [18]

The main goal of the Colon Cancer Family Registry (CCFR), an international consortium comprising 7 institutions from the USA, Canada, and Australasia. [18]

This database allowed for the differentiation between sporadic and familial forms of colorectal cancer in the subsequent year. These distinctions formed the basis for preventive, early diagnostic, and therapeutic strategies for colorectal cancers. [19]

Scientific research into the distinction between sporadic and hereditary cancers within these databases has yielded numerous conclusions that now play a crucial role in primary and secondary prophylaxis, optimal screening methods, and treatment approaches:

- Assessing the therapeutic effectiveness of extensive colectomies [20];
- Creating a model for distinguishing hereditary colorectal cancers from sporadic ones that exhibit microsatellite instability based on hyper-methylation, as well as morphological and clinical criteria [21];
- Comparing the diagnostic values obtained through IHC (Immunochemistry) tests against PCR (Polymerase Chain Reaction) [22];
- Factors that influence the adherence to screening programs [23]
- Smoking as a risk factor and NSAIDs emerging as a protective factor [24];
- The potential reduction of colorectal cancer risk through phytoestrogen intake [25];
- Estrogen-progesterone therapy [26];
- BMI, as underweight and obese postmenopausal women with colon cancer face an elevated risk of death, with comorbidities potentially contributing to this increased risk [27];
- Multiparity and pregnancy decrease the risk of colorectal cancer; studies showed an approximately 30% – 50% lower risk of gravidi-ty-associated colon cancer when considering parity. A rise in gravidity and parity appeared to show a declining trend in rectal cancer risk (p for trend = 0.07). In comparison to women with an equal number of pregnancies and live births, those who were nulligravid and nulliparous faced a 40% - 60% increased risk of colon cancer. Additionally, having one more pregnancy than live birth hinted at a potential decrease in both colon cancer and rectal cancer risk. Furthermore, there was a suggestion of an increased risk of MSI-high tumors in connection with nulligravidity and nulliparity. [28]
- Smoking increases the risk of rectal cancers in patients with Lynch syndrome [29];
- Physical activity decreases the risk of colon cancer [30].

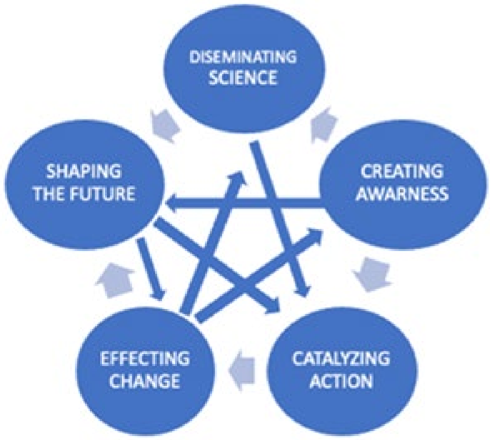
In 2007, the registry of familial colorectal cancers became an international resource for the epidemiological study of colorectal cancers, employing two distinct recruitment strategies: population-based (tracking patients with colorectal cancer and identifying the proband through MSI testing) and clinic-based (identifying families with a genealogical history of cancers). This resource supports an ongoing, comprehensive research initiative that spans various fields and disciplines. The extensive and well-defined resource is open to the wider scientific community for studies on colorectal cancer. [31]

Western Countries Which Have Adopted Best Practice Guidelines

United States of America

In the USA, the implementation of screening recommendations for Lynch syndrome involved the collaboration of the CDC in 2009, resulting in the "Evaluation of Genomic Applications in Practice and Prevention (EGAPP) recommendations for Lynch syndrome. [32]

Figure 1: xxx



Health outcomes are the ultimate goal, driven by the 5 domains of influence. Disseminating science can include publication of findings in peer-reviewed journals, presentation at conferences, or through other media channels. Creating awareness involves receiving recognition and may include awards, general awareness, or acceptance of a concept or findings by the scientific community or policymakers, generating new discussion. Catalyzing action may include partnerships and collaborations, technology creation, congressional hearings or bills, or introduction in practice. Effecting change may include building public health capacity, legal or policy change, cultural, social, or behavioral change, or economic change. Shaping the future may include new hypotheses or strategies, implementation of new programs/ initiatives, or quality improvement." [33,34]

The genetic testing standard for hereditary colorectal cancers and polyps, set by the American College of Medical Genetics and Genomics, underwent its latest revision in 2021. It mandates universal testing for colorectal and endometrial cancers, irrespective of age at diagnosis, using techniques such as immunohistochemistry (dMMR testing) or molecular biology (microsatellite instability testing). Both methods are considered interchangeable alternatives.

Simultaneously, The International Mismatch Repair Consortium (IMRC) operates as a global collaboration comprising over 115 researchers from 59 centers/clinics across Africa, Asia, Australasia, Europe, North, and South America. These researchers are engaged in clinical care and/or research related to Lynch syndrome families. Professors Jenkins, Macrae, and Haile have established this consortium, harnessing the expertise of leading groups worldwide, facilitated by the International Society for Gastrointestinal Hereditary Tumors (InSiGHT) and the Collaborative Group of the Americas on Inherited Colorectal Cancer (CGA). Cumulatively, the IMRC possesses pedigree data for more than 8,800 Lynch syndrome families, encompassing over 20,000 confirmed carriers of germline mutations in mismatch repair genes. [34]

Canada

Canada initiated the registry for hereditary colorectal cancers in 2011 following a multidisciplinary consensus involving experts in genetics, gastroenterology, surgery, oncology, pathology, and healthcare systems. This collaboration resulted in the establishment of five consensus statements:

- Consensus Statement #1: Hereditary colorectal cancer registries will improve the identification of individuals with an elevated risk of hereditary colorectal cancer.

- Consensus Statement #2: Hereditary colorectal cancer registries will increase access to suitable clinical and genetic screening for individuals at increased risk of colorectal cancer.

- Consensus Statement #3: Increased access to clinical and genetic screening will contribute to reducing the occurrence of colorectal cancer and enhancing survival rates among relatives who are carriers at risk.

- Consensus Statement #4: Every province's population should have access to a provincial hereditary colorectal cancer registry.

- Consensus Statement #5: A network of hereditary colorectal cancer registries in Canada would facilitate both clinical care and collaborative research. [35]

The latest recommendation derived from the Canadian hereditary colorectal cancer registry is that incorporating universal screening within a publicly funded system will enhance the effectiveness of identifying Lynch syndrome patients.

Given potential limitations in genetic testing and counseling resources within public systems, the integration of secondary screening involving BRAF and MLH1 promoter hypermethylation testing is crucial for further enhancing efficiency. [36,37,38]

United Kingdom

In February 2017, the National Institute for Health and Care Excellence (NICE) issued updated diagnostic guidance: Pathology departments at 14 hospital trusts in the Yorkshire and Humber region of the United Kingdom were requested to submit material from patients aged 50 years or older with newly diagnosed colorectal cancer between April 1, 2017, and March 31, 2019, for Lynch syndrome screening. The testing protocol included immunohistochemistry for MLH1, PMS2, MSH2, and MSH6, followed by BRAF mutation analysis with or without MLH1 promoter methylation testing if MLH1 loss was identified. A total of 3,141 individual specimens were submitted from 12 departments, comprising 3,061 distinct tumors and 2,791 prospectively collected CRC patients. dMMR was observed in 15% of cases. Among cases with MLH1 loss, 76% exhibited a detectable BRAF mutation, while 77% of the remaining cases showed MLH1 promoter hypermethylation. Among patients included in the final analysis, 81 (2.9%) had indications for germline testing.

The implementation of LS screening through the NICE diagnostics guidance pathway can be effectively executed on a large scale, identifying a substantial cohort of patients with dMMR. This data is used to refer patients to regional clinical genetics services and also plays a crucial role in shaping treatment routes, including decisions regarding adjuvant/ neoadjuvant chemotherapy and immunotherapy. [39]

Australia

The first case of Lynch syndrome was identified by the Genetic Services Western Australia in 1994, shortly after pathogenic mutations in MMR genes were established as the underlying cause of the condition previously referred to as HNPCC. Over the following 11 years until 2004, there were 1 to 4 new cases identified annually. This observation was deemed lower than anticipated, given that the annual incidence of CRC in WA was approximately 1,000 cases during this period and considering the assumption that LS contributes to 1–3% of all CRC cases.

Australia has a single registry for familial cancers, which, starting in 1994, compiled data accompanied by Lynch syndrome screening results using routine IHC testing of MMR or MSI through PCR for cancers in patients under 60 years old. This approach quadrupled the annual number of identified LS cases. [40]

The Netherlands

The Dutch Hereditary Cancer Registry was established in 1985 with the support of the Ministry of Health (VWS). The main goals of the registry are:

I. Facilitating the identification of families with hereditary cancer;

II. Encouraging high-risk individuals' participation in surveillance programs;

III. Ensuring the continuity of lifelong surveillance examinations;

IV. Promoting research, especially for enhancing surveillance protocols.

Currently in the Netherlands, the diagnosis of Lynch Syndrome relies on a nationwide guideline for MSI analysis, introduced in January 2008 by the Netherlands Comprehensive Cancer Organization. Leveraging the Netherlands Cancer Registry [41], this guideline facilitates dynamic enhancements in Lynch Syndrome Management. This guideline closely resembles the MIPA (Multitesting Indicated by a Pathologist) criteria. MSI analysis (along with IHC of MMR proteins) is requested by pathologists for patients recently diagnosed with CRC or endometrial carcinoma under the age of 50, or those with two LS-associated tumors (including synchronous and metachronous CRCs) before 70. Cases with multiple LS-associated cancers are documented in PALGA, the nationwide network and registry of histopathology and cytopathology in the Netherlands [42]. For MSI analysis prompted by a positive family history, referral to a clinical geneticist is advised. In these instances, MSI analysis is generally conducted when the (revised) Bethesda or Amsterdam Criteria are met, contingent upon the availability of archival paraffin-embedded tumor tissue. [43,44]

Sweden

The National Swedish Registry (now known as the SCRCR) was founded in 1995, with a focus on rectal cancers, and later expanded to include colon cancers in 2007. The use of a unique personal ID number by the SCRCR enables the tracking of patient data over time. The study indicated that a minority of young CRC patients received genetic counseling, which goes against clinical guidelines. Consequently, hereditary CRC is likely to be underdiagnosed, even within the younger population. [45,46]

In Sweden, families suspected of having Lynch syndrome are directed to the regional department of clinical genetics in Umeå, Uppsala, Stockholm, Linköping, Gothenburg, or Lund for counseling and genetic testing.

Switzerland

The present approach to Lynch syndrome screening in Switzerland incorporates two tumor-based assessments (IHC and BRAF V600), followed by DNA sequencing. Germline DNA screening exhibits almost 100% accuracy, thus identifying all instances of Lynch syndrome and eradicating false negative and false positive diagnoses. This strategy also averts the possibility of CRC patients being lost to follow-up and prevents deaths stemming from undetected LS cases. Additionally, it identifies a greater number of cancer-free relatives and new CRC cases at early stages through colonoscopy screening. Despite the notable expenses linked to providing DNA testing for all CRC patients, universal LS screening enhances the overall effectiveness of genetic testing at a reasonable cost. [46]

Iceland

Iceland introduced universal screening for Lynch syndrome by conducting immunohistochemistry for MMR proteins on resected colorectal carcinomas and endometrial carcinomas in 2017. The primary challenge involves establishing a robust implementation of the screening algorithm by pathologists and ensuring accurate referrals for genetic counseling. One suggested solution is the automatic application of IHC staining on all CRC and EC cases, with any abnormal staining outcomes promptly reported to designated pathologists overseeing the ordering and interpretation of additional molecular tests. When genetic counseling is recommended, effective communication with the surgeon in charge, and ideally, the genetic counselor, is of paramount importance, preferably through verbal means [47].

Austria

The Austrian AGO (the workgroup for oncological gynecology) recommends IHC tissue screening for both type-I and type-II endometrial cancers for patients below the age of 70, and for endometrioid and clear-cell ovarian cancers, irrespective of patient age. If necessary, IHC can be supplemented with MLH1 promoter hypermethylation testing and/or microsatellite instability analysis on tissue samples. To confirm a Lynch syndrome diagnosis, identifying a germline mutation through molecular genetic testing of the mismatch repair genes using the patient's blood is required. This genetic examination should be conducted directly without prior tissue screening if the family history of LS-associated cancer patients aligns with either the Amsterdam II or the revised Bethesda criteria.

There are two distinct tumor tissue-based screening processes that significantly raise suspicion of Lynch syndrome:

- IHC identification of the absence of any of the four relevant MMR proteins: MLH1, MSH2, MSH6, or PMS2 in tumor tissue.
- Detection of MSI by examining five specific microsatellites in tumor DNA using RT-PCR; the presence of two or more positive markers indicates a strong suspicion of Lynch syndrome.

However, for individuals with a confirmed LS-associated carcinoma and a positive family history in accordance with either Amsterdam II or the revised Bethesda criteria, the aforementioned screening protocol should be bypassed, and a germline analysis should be promptly provided.

In alignment with the 2014 National Comprehensive Cancer Network guidelines, AGO Austria advises the testing of tumor tissue for Lynch syndrome in all women with endometrial carcinoma (both types I and II) who are under the age of 70. [48]

Furthermore, AGO Austria also advocates for the performance of these tests regardless of the age at diagnosis for endometrioid and clear-cell ovarian cancers. Even in cases where all screening outcomes yield negative results, if the family history still strongly indicates the possibility of Lynch syndrome (i.e., Amsterdam II or revised Bethesda criteria are fulfilled), comprehensive molecular genetic testing of all identified LS-associated genes should be contemplated.

Japan

Until the early 2000s, Lynch syndrome screening predominantly targeted cancer patients with high-risk attributes as per the Amsterdam II criteria or the revised Bethesda guidelines. However, in subsequent years, the practice of universal screening, involving MMR IHC and/or MSI analysis (with or without age restrictions), gradually took precedence over these population-based selections. Consequently, the approach to identifying Lynch syndrome has transitioned towards widespread universal screening [49].

Today, the advent of cancer genomic-based precision medicine has ushered in the use of Next-Generation Sequencing (NGS) for comprehensive somatic and germline MMR sequencing, spanning selected-gene or genome-wide assessments.

However, the main challenge of universally applying sequencing for germline MMR analysis pertains to the assessment of pathogenicity, which relies on the public genome database. This arises due to the substantial presence of Variants of Uncertain Significance (VUSs), and the eventual transition to a pathogenic level over time.

High rates of gastric cancer were observed in Japanese individuals affected by Lynch syndrome, and this occurrence was linked to Helicobacter pylori infection. The deficiency of MMR proteins was found to contribute to the formation of malignant tumors in LS patients. [50]

Advancing Lynch Syndrome Management

Results of Universal Screening

Presently, there are differing approaches to tumor testing methods across hospitals, resulting in a range of 0 - 19% of patients having incomplete mismatch repair deficiency test results. Due to the existing gaps in Lynch syndrome testing and referrals, additional efforts are required to establish effective approaches for seamlessly integrating LS testing into clinical practice; this could serve as a blueprint not only for hereditary cancers but also for broader genomic medicine. The implementation of standardized reporting may assist clinicians in comprehending tumor test outcomes and initiating appropriate subsequent steps.

Extending Testing to Other Organs

In 2020, Stanford University proposed the implementation of MMR testing for all digestive tract cancers, not solely limited to colon cancers. This recommendation stemmed from a study involving 1,425 consecutive malignant neoplasms that underwent MMR testing post-surgery. Surprisingly, 7.2% of these cases exhibited dMMR. The highest prevalence rates were observed for gastric cancers at 10%, followed by colorectal cancers at 9.1%, pancreatic cancers at 5.3%, and gastroesophageal cancers at 4.5%. [51]

Improving the Implementation of Diagnostic Guidelines

Based on these findings, and starting in 2008, routine MSI and/or IHC testing was recommended for all CRC patients under 60 years of age in Western Australia, regardless of their family cancer history. However, the systematic implementation of these tests at a population level for LS identification has proven to be challenging due to the need for collaboration and effective communication among various disciplines, including gastroenterology, pathology, surgery, oncology, and medical genetics. By the end of 2012, GSWA had identified 115 unrelated LS families with MMR gene mutations, comprising 40 MLH1, 51 MSH2, 11 MSH6, and 9 PMS2 germline mutations.

A significant number of Lynch syndrome patients detected through screening did not have a family history of cancer meeting the Amsterdam or Bethesda criteria, highlighting the importance of laboratory screening tests in their identification. Findings strongly suggest that the routine use of MSI and IHC screening for CRC has substantially improved LS detection in Western Australia.

Drawing from past experience with population-based screening in Western Australia, three crucial components take shape that are essential for the successful implementation of LS screening in other states or regions:

I. Reflex IHC testing should be conducted through accredited pathology services with consistent quality control systems in place.

II. The establishment of a centralized reference laboratory at the state or regional level is essential for MSI testing, serving to validate any abnormal or uncertain IHC results initially detected by pathology service providers. This is a crucial mechanism in preventing unnecessary referrals of individuals with false-positive IHC results to familial cancer clinics. In previous observations, the MSI test displayed reduced susceptibility to interpretational errors and greater potential for standardization, compared to IHC.

III. Thirdly, a pivotal aspect is the presence of state or regional-wide LS coordinators, ensuring that all red flag cases discovered by laboratory testing are promptly referred to familial cancer clinics before patients' health deteriorates significantly or life-threatening situations arise. [51]

Defining the Phenomenon of Genetic Anticipation

Genetic anticipation is a phenomenon where symptoms of a hereditary disease appear at an earlier age and/or are more severe in successive generations. [52]

A 2009 study examined the evolution of 125 families, encompassing 824 individuals (with 427 being female). This study yielded a quantified inference about anticipation. It revealed that the cancer appeared 3 years earlier from generation to generation. [53]

Since Alfred Whartin's initial description of Lynch syndrome in 1925, there has been documentation of a gradual reduction in the age of CRC diagnoses across successive generations. Over the years, a multitude of studies have examined the possibility of anticipation in this syndrome, showing variances from 3 to 13 years. [54]

Cost-Effectiveness Analysis for Universal Screening

A cost-effectiveness analysis conducted in Switzerland examined universal screening for Lynch syndrome in individuals diagnosed with colorectal cancer, followed by cascade genetic testing of their relatives. The Evaluation of Genomic Applications in Practice and Prevention working group has endorsed the practice of screening for LS among all newly diagnosed cases of CRC, regardless of age and family history, followed by the sequential testing of blood relatives. [55] The study assesses the economic viability of the alternative approach to identifying LS cases, considering the perspective of the Swiss healthcare system.

An analytical framework was formulated, merging decision trees with Markov modeling to calculate the cost-effectiveness of universal LS screening for individuals newly diagnosed with CRC, followed by cascade testing. Markov models encompassed four states: well-being, CRC, metachronous CRC (mCRC), and death. When diminishing the CRC risk in LS-diagnosed relatives to 25%, the program's cost rose to CHF

103,385 per QALY, surpassing the cost-effectiveness threshold. Universal LS screening combined with the sequential testing of relatives is cost-effective in around 80% of cases. The number of averted deaths is linked to yearly shifts from a state of health to CRC, and from CRC to death, which are significantly lower in populations subjected to testing and screening. [56]

Contemporary Challenges

Among path_MMR carriers undergoing colonoscopy surveillance, deaths resulting from non-CRC LS surpassed those from CRC. Addressing mortality associated with non-CRC presents a significant contemporary medical challenge in managing Lynch syndrome. [57]

International consortia

Genturis

The European Reference Network (ERN) is a network that connects healthcare providers and specialized healthcare centers, aiming to enhance access to diagnosis, treatment, and the delivery of exceptional healthcare services to patients diagnosed with rare diseases, regardless of their location in Europe. The governance of ERN also involves the participation of patient representatives. ERN employs international consensus guidelines for patient recruitment:

- Endorsed guidelines for Lynch, and polyposis, and hereditary CRC. The Manchester International Consensus Group recommendations for the management of gynecological cancers in Lynch syndrome

- Endorsed guidelines for Lynch, and polyposis, and hereditary CRC. Endoscopic management of Lynch syndrome and of familial risk of colorectal cancer – the European Society of Gastrointestinal Endoscopy (ESGE) Guideline.

- Endorsed guidelines for Lynch, and polyposis, and hereditary CRC. European guidelines from the EHTG and ESCP for Lynch syndrome – an updated third edition of the Mallorca guidelines based on gene and gender.

Middle East Network on Hereditary Colorectal Cancer

An association of medical professionals from Middle Eastern and North African (ME/NA) countries was established to enhance the identification and care of LS families. The organization conducted a survey in order to assess the existing healthcare services for families with LS in this region.

The acknowledgment and management of Lynch syndrome within ME/NA countries are suboptimal, leading to the majority of LS families in the area remaining unidentified. Future initiatives should focus on raising awareness about Lynch syndrome among both the public and medical practitioners and on improving the infrastructure in these countries. [58]

Future initiatives should concentrate on raising LS awareness among the public and medical professionals and enhancing the infrastructure within these nations.

Moreover, it's crucial to establish registries for families with hereditary cancer. This step aims to motivate participation in prevention programs and ensure the seamless continuation of lifelong surveillance initiatives. [59]

Countries With Limited Adoption of Western Best Practice Guidelines

Numerous countries continue to exclusively employ clinical diagnostic criteria, namely Amsterdam and Bethesda. The majority are in Asia and Africa, although most of these countries lead the diagnosis until genetic confirmation.

In Taiwan only a small number of medical centers offer Lynch syndrome diagnostics [60]; For a long time, China relied solely on the clinical diagnostic criteria. [61] In 2021, knowledge about LS-related EEC among the Chinese population remained scarce. The most extensive Chinese multi-center population study was undertaken in 2021, involving an analysis of 95 cases of dMMR. [62]; Based on the Singapore Polyposis Registry, an analysis was conducted on 59 unrelated families meeting the clinical diagnostic criteria, specifically Amsterdam II, and revised Bethesda. All identified genetic abnormalities involved MLH1 and MSH2, leading to the detection of LS in 17 families. [63] In a study conducted at a tertiary referral center focused on the rising cases of early-onset colorectal cancer, histopathologically processed tumor specimens revealed a potential increase in Lynch Syndrome incidence among CRC patients in Indonesia. They identified 32 likely cases of LS. [64]; The 2011-founded Russian Society for Clinical Oncology lacks specific recommendations for hereditary colon cancer. Lynch syndrome treatment seems to lean towards immunotherapy, with no clear genetic counseling recommendations. [65]

In South Korea, the largest study, which analyzed colo-rectal cancers recorded over a span of 10 years involving 5,520 patients, applied the Amsterdam II criteria to identify patients with LS. Only 1.3% of participants met these criteria, and their tumors were tested for microsatellite instability. Out of the latter group, only 25 patients, representing 6.9%, tested positive for MSI. Genetic tests were conducted on half of this latter group, yielding positive results for only 11 patients. [66]

Qatar, Saudi Arabia, and Pakistan conducted studies that represent foreplay for genetic testing, but no standardization is available for the moment [67, 68, 69].

African countries

South Africa consists of 9 provinces, with an approximate mid-year population of 58.78 million.

Genetic services are primarily extended to recently diagnosed LS patients and their family members within these areas through academic institutions situated in the Western Cape. Additional initiatives reach out to smaller neighboring towns and rural regions. [70-73]

Colonoscopic surveillance for at-risk family members is arduous and costly in resource-limited settings. Nevertheless, previous LS studies in the Western Cape region of South Africa have demonstrated that identifying the causative mutation significantly streamlines and reduces surveillance expenses. [74]

Morocco lacks a national protocol, the largest study involved 385 patients; for 214, MMR IHC testing was conducted; 159 underwent BRAF mutation testing as well. Among those diagnosed with LS, 35.6% were under 50 years old. These findings underscore the significant prevalence of CRC in young patients and the frequent occurrence of rectal localizations within the Moroccan population. [75]. In Tunisia, diagnosis is primarily based on clinical criteria. [76]

Identification of Lynch Syndrome Risk Variants in the Romanian Population

So far, two important research initiatives have been conducted in Romania.

After sequencing 61 CRC patients, 11 uncommon coding variants were identified in CRC genes: six in MLH1, one in MSH6, one in PMS2, and three in APC. ClinVar19's literature and clinical trial submission data for pathogenicity assessment were cross-referenced. Among the 11 variants, six were previously documented in ClinVar, each with a frequency below 1% in the ExAC database. [77]

Paget's Disease of the Bone and Lynch Syndrome: An Exceptional Finding

The patient's medical record included a diagnosis of well-differentiated rectal adenocarcinoma at the age of 34, which was treated with chemotherapy and radiotherapy, resulting in secondary amenorrhea, as well as the removal of an oesophageal papilloma through endoscopy. Furthermore, she had undergone surgery for three lumbar herniated discs and dealt with autoimmune chronic thyroiditis while maintaining normal thyroid function.

Concerning her family's medical history, the patient's mother had been diagnosed with polyostotic PDB, impacting her skull, femur, and spine at 44. Additionally, her father passed away from colorectal cancer at the age of 47. As of now, no targeted genetic testing has been conducted.

Although the simultaneous occurrence of PDB and LS has not been documented previously, instances of two distinct autosomal dominant conditions co-occurring, albeit rare, have been previously reported. [78].

DISCUSSION

The Romanian Society for Lynch Syndrome is working, through the national Lynch syndrome network, to align Romania with the countries practicing optimized management of LS patients.

CONCLUSIONS

Globally, colorectal cancer ranks as the first or second most common cancer in both sexes. Lynch syndrome, the most prevalent autosomal dominant genetic syndrome, predisposes to the development of numerous cancers, primarily driven by a genetic defect in MMR proteins. The colon is most frequently affected, with up to an 80% elevated risk of neoplasia compared to the general population. Multiple organs can be involved, including the endometrium, ovaries, and other parts of the digestive tract, identified since the syndrome's inception. Early diagnosis, both for the proband and their family, is pivotal for primary prevention and tailored screening programs. As of 2018, distinct therapeutic approaches have been introduced, including immunotherapy [79, 80].

Currently, there are numerous guideline recommendations and countries that have implemented them. However, widespread adoption of these recommendations has the potential to enhance cancer-related epidemiological indices (incidence, prevalence, morbidity, mortality), as well as economic profiles. Additionally, the significance of enriched databases enriches our understanding of the disease's biology, which still harbors many unknowns – prognostic factors for cancer onset, immuno-logical or genetic means (vaccines) of prevention, and more.

Conflicts of interest and sources of funding
The author declares no conflict of interest.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author’s institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

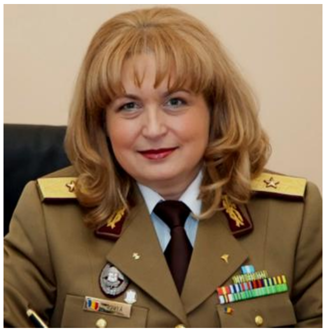
Benchmarks of the evolution and revolution of military medicine in the XXI century – Tradition, Trust, Professionalism

Florentina Ioniță Radu



Brig. Gen. FLORENTINA IONIȚĂ RADU

Commander, Central Emergency Military Hospital, Ministry ofNational Defence, Romania
Associate Professor, Titu Maiorescu University, Bucharest

There is no secret to anyone that we live in a society marked by uncertainty and unpredictability, a society in which information flows through all communication channels, both in cyberspace and in mass media. Therefore, it is increasingly difficult for the „modern man” to decide upon the veracity and value of the informational content so that, eventually, based on the latter, he can upgrade his knowledge in any area of interest.

In such a context, it is difficult for society to control its evolution and to identify valuable markers that would ensure a valid growth in time and space. Lacking history, hierarchy, elite, rules and order, one can talk neither about the development of an organization nor about the development of society as a whole.

I think we have all passed, in recent years, through a "period of resistance" to the wave of non-values that invaded us and created an organic need to protect and preserve the values our parents and grandparents taught us. Despite the appearance of resignation, the accumulation of such energy has made us stronger, more aware of our role and this made us persistent and gave us the power and the chance to change our future and our children’s future.

Returning to the reason that brought us together, by means of this page, you – the reader and me – the author, I can say without any doubt that every cell of my being has reacted with emotion at the course and unrest of the last years of military medicine. It was only when I became the Commander (General Manager) of the "Dr. Carol Davila" Central Clinical Emergency Military Hospital (SUUMC), that I fully understood the huge potential of this noble profession – military doctor – potential generated by the excitement of the trust and respect offered each day by the public opinion in general and especially by citizens.

I have always considered that medicine is a field in which evolution ignores borders, bureaucratic rules, customs and paradigms, because trying to rescue somenone’s life is such a pure and noble approach that no sacrifice for this purpose can ever be considered too big.

This year the "Dr. Carol Davila" Central Clinical Emergency Military Hospital, a symbol for the history of Romanian society, celebrates the honorable age of 185 years of tradition, trust and professionalism, dedicated to research, development and innovation in medicine. 185 years in the service of life, without any deviation from the fulfillment of the two oaths: the military oath and Hipocrate's oath.

We should always keep, in our minds and hearts, the memory of those who, on the battlefield of the two World Wars, nursed their fellows and some of them even lost their lives trying to rescue the latter, the persistence of the struggle with their own limits taking care of the victims of the earthquake that shook Bucharest in March 1977; the emotion lived when faced with the young soldiers, victims of the construction of Transfăgărăşan and of the Danube – Black Sea Canal. Recently, the victims of the tragic fire at Club Colectiv were a challenge for the doctors and nurses in our hospital. All the departments of the hospital worked as a real efficient and dedicated team having only one purpose: to save the lives of the victims who were our patients.

During 185 years, together with the Romanian Army, we have been in the service of the country and of the population, doing our best in our duty with modesty, professionalism, ethics and team spirit. We did not pose as mentors, although here, in this area of health, the foundations of medicine, pharmacy and education in this field in Romania were laid. Medical and surgical specialties were also born here, specialties that today are spoken of as a fact, not as a gift from our ancestors, military doctors – thoracic surgery, urology, epidemiology etc.

The only thing military medicine was deprived of until now, is "a single voice of professionals" in this field, segment considered by most of our civil colleagues relatively narrow as area of specialty and therefore lacking the capital injection necessary to ensure its technical and cutting-edge technology, which apparently decreased our competitiveness in the market of medical services provided. Not true! In the absence of facilities, the human resource of this system accepted the professional challenge and approached a sphere of increasingly complex pathology, and on the other hand, the interdisciplinary collaboration has strengthened human links and increased our performance as professionals. It is true that until three years ago, we may not have had the latest surgical technologies but we beat cancer through the physician's sharp spirit, the surgeon's, the pathologist's and oncologist's experience.

Three years do not mean anything for a hospital, but for someone diagnosed with a relentless disease they mean everything... This was one of my thoughts that motivated me to develop centers of excellence – assigned and equipped to the highest standards – capable of providing prevention, treatment and monitoring of disease in the oncologic pathology, strokes, cardiovascular diseases and digestive diseases; lung transplant – a medical and surgical activity of high human and professional performance, which also involves a great responsibility assumed by SUUMC, on medium and long term, for patient's life quality, service which is not available at this time, in any other public hospital in Romania; neurological and neuromotor rehabilitation center for the veterans from the operation theaters.

Romania's geopolitical and geostrategic situation, as a state located at the EU and NATO border, obliges me, at the same time, to analyze the development of the operational medicine component in the Central Military Clinical Emergency Hospital "Dr. Carol Davila", so that, in wartime, we can be prepared to face the specific challenges related to the pathology and casuistry of a military confrontation.

Both as a doctor, and especially as the manager of the Central Military University Emergency Hospital "Dr. Carol Davila", I understand that the expectations of the whole society towards military medicine are very high, whether we speak of peace or war. People expect us to be a performant regional hospital, which provides at safe and high standards, a medical act comparable to that granted by a specialty hospital from abroad, while in wartime the hospital should become an elite military medical facility, ROL 4, able to provide medical care to the standards required by our NATO allies.

With a background of 185 years, the Central Military Clinical Emergency Hospital "Dr. Carol Davila", returns in force, as an important player on the market of medical services in Romania and elsewhere, proving that to the three qualities that have pierced the veil of history – TRADITION, TRUST, PROFESSIONALISM –

we should add the key to success in order to ensure the evolution of this type of institution, within the criteria imposed by the information society, consisting of flexibility, predictability, resilience and responsiveness in the case of a crisis or disaster.

As arguments in support of the above, I would point out some key milestones of the work of the last three years, namely, that SUUMC is the only institution in the medical network of the Ministry of Defence running projects from European funds for research, development and innovation in the medical field. It is connected to military medical centers in the Balkans, by means of the collaboration platform of telemedicine type, IMIHO. The hospital has developed collaboration agreements with major centers in the field, in the country and abroad (Belgium, Austria, Turkey and Serbia) to conduct training programs for medical staff and it is a serious instruction and training institution for students and residents, as a consequence of the extension of academic and university partnerships.

At the beginning of a new stage of life, I hope that The Romanian Journal of Military Medicine, in this new format, supported by a high scientific editorial board, will fulfill its objective to disseminate knowledge, to bring added value to the market of specialized publications in this field, from Romania and from abroad, to support the research activity and to motivate young people who make their first steps on the road to a career dedicated to the most precious thing that we all receive: health.

As a team player who strongly believes in the power of military medicine elite, in the interdisciplinary dialogue of this discipline, I assure you that I will support this approach, as I have already done it so far, in order to increase its quality every year and to borrow from the brilliance of the historic celebration of 185 years from the signing of the birth certificate of the Army Hospital.

REVIEW ARTICLE

Article received on February 12, 2016 and accepted for publishing on March 1, 2016.

The use of low-intensity ultrasound system in Orthopedics for treatment of fractures

Alexandra Șopu[1]

INTRODUCTION

The treatment of non-union or delayed union of fractures includes a growing number of approaches and techniques, one of which is bone growth stimulation using low-intensity ultrasound (LIUS). The treatment is effective, painless and safe. Currently, Exogen is the only device marketed worldwide that uses LIUS to influence the fracture healing process.

THE HEALING PROCESS OF THE FRACTURED BONES

All the fractured bones have to go through a healing process. This is true in cases of surgery or injury. The process of bone healing has three stages. The first stage is inflammation. This starts when the bone has been fractured. Bleeding always takes place in the area of the fracture. This leads to clotting of blood and inflammation in the area. This provides the framework of a new bone. The second stage is bone production. With time, the clotted blood formed in the inflammation stage is replaced by cartilage and fibrous tissues. As the healing continues, the hard callus replaces the soft callus. This can be seen by x-rays some days after the fracture [1, p 20]. The last stage is bone remodeling. This stage goes on for months. In this stage, the bone continues to become compact and returns to its original shape and structure. The blood circulation in the area of the fracture improves. Once some bone healing has taken place, weight bearing encourages the bone remodeling stage [2, p 99].

THE EXOGEN ULTRASOUND BONE HEALING SYSTEM

This is an approved and clinically tested system for treatment of bone fractures. Exogen makes use of the painless ultrasound waves in order to activate the cells that are near the site of the fracture. This speeds up the natural repair process [3, p 1999].

Clinical studies have shown that the system accelerates the healing process of the fractured bones by 38 % in acute fractures [4, p 655] and 86% in non-union or delayed union. It has been shown that Exogen can improve the fracture healing process of older people, those who take tobacco and those who are obese, cases in which the healing process might be delayed. Exogen system can accelerate the process of healing as much as 50 % for the patients who smoke [6, p 254].

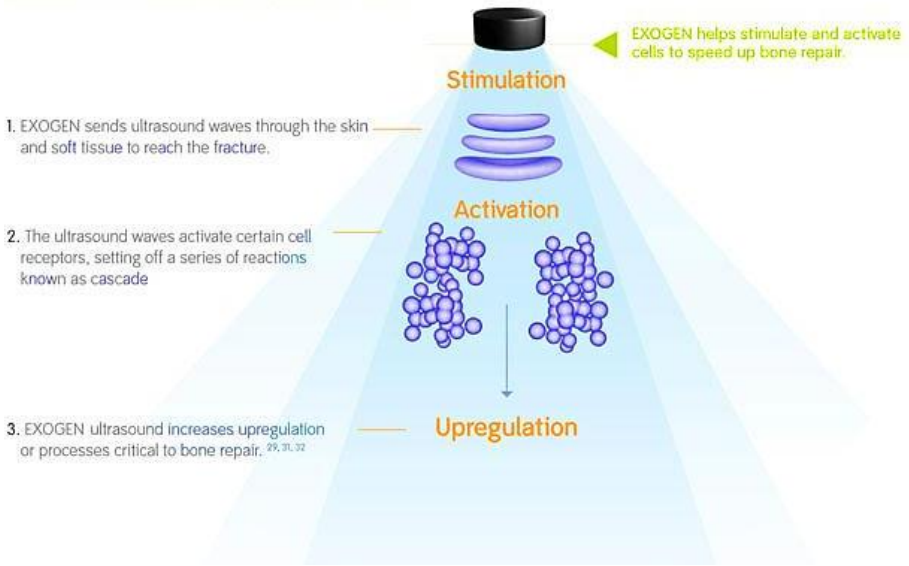
The picture below offers a basic explanation of how Exogen works at the cellular level.

To enhance bone healing, Exogen releases low intensity pulsed ultrasound waves at the point of the fractured bone. This jump-starts the natural healing process of the body. The waves move through the skin and the soft tissues to stimulate the critical cells involved in bone healing.

---

[1] Queen Elizabeth Hospital Birmingham, United Kingdom

Figure 1: The way Exogen Accelerates the Healing Process of a Fractured Bone [14]



EXOGEN helps stimulate and activate cells to speed up bone repair.
Stimulation
1. EXOGEN sends ultrasound waves through the skin and soft tissue to reach the fracture.
Activation
2. The ultrasound waves activate certain cell receptors, setting off a series of reactions known as cascade
3. EXOGEN ultrasound increases upregulation or processes critical to bone repair. 29, 31, 32
Upregulation

In order to understand the role that the ultrasound plays in healing of the fractured bones, there is a need to understand what it is and how it works. It uses transcutaneous acoustic energy. The piezoelectric crystal produces sound waves which are transmitted through the various body tissues to make a number of changes which are implicated in the tissue healing [8, p 1098]. The density of the tissue is directly proportional to the sound waves that the tissue absorbs. The bone possess high density which makes the ultrasound waves to target the areas which may be affected or have bony abnormalities.

Low intensity pulse ultrasound (LIPUS) specifically works as a potential noninvasive therapeutic in healing of fractures. The waves which are produced by LIPUS introduce micromechanical stress in the area that has been fractured. This stimulates the cellular and molecular responses that are involved in the normal fracture healing. The osteogenic and angiogenic effects caused by the administration of LIPUS are non-thermal. The effects are mechanical in nature with a temperature variation of less than 10C [9, p 802].

The optimum parameters used to archive the maximum benefits of LIPUS are: a pulse width of 200us, an intensity of 30 Mw/cm2 and a 1.5 MHz frequency repeated at 1 kHz every day for 20 minutes [6, p 254].

HOW ULTRASOUND EXERTS MECHANICAL STRESS

There are two mechanisms by which LIPUS induces the mechanical stress in tissues. First it achieves it by displacement of the ends that are fractured and secondly by cavitation.

Research shows that displacement of the fractured ends occurs in at Nano metric scale [9, p 802]. This then stimulates the cellular and the molecular pathways which are involved in the bone healing process [10, p 1022]. It has been shown that LIPUS causes micro motion at the hard and soft tissues interface also. This action produces a mechanical stimulus that is more salient to the integrin mechanoreceptors which take part in osteogenic differentiation and cellular signaling. However it is not yet clear through the available research which displacement mechanism is dominant [11, p 703].

The second mechanism involves the acoustic streaming and cavitation. This mechanism promotes the idea that the sound waves that are emitted from LIPUS allow the accumulation of gas bubbles in the tissues and the cells [12, p 411]. This creates a cavity which gives room for the acoustic streaming. The streaming leads to turbulence or circular flow in the fluids from the tissues as the sound waves move around the bubble of gases. The acoustic streaming produced increased cell permeability. Once this has happened, the blood pressure rises in the area where the fracture has occurred. The increase in the blood pressure leads to the acceleration of healing by ensuring that there is sufficient gas exchange and the delivery of nutrients to the site. When the cavitation is not stable, the bubbles burst and the resultant energy stimulates the surrounding tissues [13, p 2642].

THE EFFECT OF LIPUS ON CELLS AND MOLECULES

There have been studies that have demonstrated the ability of LIPUS to promote fracture healing through the alteration of molecular and cellular mechanisms which are involved in the process of healing. Integrins are crucial in signaling modulation involved in fracture healing [14, p 345].

They act as mechanoreceptors and are also reactive to pressure changes and vibration caused by LIPUS in the cells environment. The mechanical stimuli increase the clusters of integrin on the fibroblasts. They also up regulate the mRNA expression of the integrin in osteoblasts [15, p 284]. The changes that occur enhance the sensitivity of the respective cells to motion and increase the cells intercellular signaling capacity. An important outcome associated with the intercellular signaling induced in the osteoblasts is the increased activation of ocyclooxygenase-2 enzyme.

This increases the production of prostaglandin which is critical in the mineralization during the process of endochondral ossification especially on the soft callus [16, p 660]. The endochondral ossification which is enhanced by LIPUS leads to formation of the bony callus by the process of augmented mineral deposition [17, p 77].

LIPUS also stimulates the differentiation of the cells which are involved in the process of fracture healing, chondroblasts, fibroblasts, mesenchymal and osteoblasts. Additionally, it increases the way aggrecan expresses itself [18, p 1957]. Aggrecan is a stimulator of chondrogenesis. Presence of aggrecan accelerates the differentiation of chondroblasts into chondrocytes. The production of chondroitin sulfate at the site of injury is accelerated by the presence of more chondrocytes.

Chondroitin sulfates are essential components in supporting bonny and cartilaginous structures. Because of the cavitation process aforementioned, LIPUS increases pressure at the site of injury due to the increase in the vascular permeability [19, p 727]. The increase in pressure has been associated with mesenchymal stem cells differentiation which enhances the development of fibro cartilaginous callous.

LIPUS increases the expression of the early osteogenic genes which include osteonectin, the insulin growth factor and osteopontin. These genes have an important role in making sure that proper osteoblast differentiation takes place [20, p 3190]. The osteoprogenitor cells from the bone marrow may also differentiate into the osteoblasts at a high rate when LIPUS is used. This will enhance the bone healing process and remodeling.

CONCLUSION

The use of low-intensity ultrasound system is a relatively new technology that has been proven to be safe and efficient in the treatment of acute fractures or in cases of non-union or delayed union. The effects at the cellular and molecular level demonstrate its efficacy.

REVIEW ARTICLE

Article received on February 17, 2016 and accepted for publishing on March 5, 2016.

A new global threat for the public safety: Zika virus

Simona Bicheru[1], Ion Ştefan[2], Marius Necşulescu[1], Diana Popescu[1], Lucia Ionescu[1], Gabriela Dumitrescu[1], Viorel Ordeanu[1,3]

Abstract: *Zika virus, the etiological agent of Zika fever, is transmitted by mosquitoes and has been affecting the South American continent starting with 2015. It was reported in several European countries, carried by the people who returned from Latin America, as reported by the health authorities in those countries. Today, according to the World Health Organization (WHO), the virus suspected to cause serious birth defects in the fetus has also been confirmed in 21 of the 55 countries of South America, but also in other states from Europe and North America. Zika virus is a single stranded positive sense RNA virus belonging to Flavivirus genus (family Flaviviridae) and was first identified in 1947 in Uganda rainforest Zika. The increased number of cases of microcephaly, in children from northern Brazil, suggested a connection with Zika virus, but it has not yet been proven. Also, the virus can be transmitted sexually and through blood or blood products. Diagnosis of the infection is made using Polymerase Chain Reaction (PCR). So far, there is no specific antiviral treatment or vaccine against the infection with Zika virus. The best form of prevention is to avoid mosquito bites. WHO has estimated that the spread of Zika virus, transmitted through mosquito bite, is "a global public health emergency". The priority is to protect pregnant women and to control the mosquitoes.*

Keywords: *Zika virus, Flaviviruses, microcephaly, Aedes aegypti, mosquitoes*

INTRODUCTION

Zika virus, the etiological agent of Zika fever, is transmitted by mosquitoes and has been affecting the South American continent starting 2015. It was reported in several European countries, carried by the people who returned from Latin America, as stated by the health authorities in those countries. Today, according to the World Health Organization (WHO), the virus suspected to cause serious birth defects in the fetus has also been confirmed in several countries from Europe: Great Britain, Italy, Netherlands, Portugal, Denmark and Switzerland.

Zika virus has been reported sporadically in Africa and Asia for several decades. Zika fever outbreaks were reported for the first time in 2007 (Yap island found in the Pacific Ocean), then in 2013 (French Polynesia). In 2015, outbreaks occurred in Africa (Cape Verde Islands) and South America (Brazil and Colombia). From here, Zika virus quickly spread to several countries in South and Central America and was finally reported in 21 countries of the region in early 2016. [1][2][3] On January 28, the World Health Organization announced that 3-4 million people in

---

[1] Military Medical Research Center, Bucharest
[2] Carol Davila Central University Emergency Military Hospital, Bucharest
[3] Carol Davila Universityof Medicine and Pharmacy, Bucharest

America could be infected with Zika virus in 2016. [4] On February 1, 2016, the WHO has estimated that the spread of Zika virus, transmitted through the bite of *Aedes aegypti* mosquito, is “a global public health emergency”.

THE ETIOLOGICAL AGENT

Zika virus is a single stranded positive sense RNA virus belonging to *Flavivirus* genus (family *Flaviviridae*) and was first identified in 1947 in Uganda rainforest Zika. It is the etiological agent of Zika fever, a viral infectious disease transmitted by infected mosquitoes. [1][2][3]

SYMPTOMATOLOGY

The incubation period is 3-12 days after an infected mosquito bite. Most infections caused by Zika virus are asymptomatic (60-80%). Symptoms are usually mild and disappear within 2-7 days without severe complications or death. The main symptoms are rash (macular or a papular exanthema that initially appears on the face and then spreads throughout the body), moderate fever, arthralgia, myalgia, headache, non-purulent conjunctivitis with conjunctival hyperemia. Vertical transmission can occur during labor (in the viremic stage) or transplacentar. The increased number of microcephaly cases in children from northern Brazil suggested a connection with Zika virus, but it has not yet been proven. Also, the virus can be transmitted sexually and through blood or blood products. [1][2][3]

TRANSMISSION

Zika virus is transmitted by mosquitoes and was isolated from species of the genus *Aedes*, such as *A. aegypti* (Figure1), *A. africanus*, *A. apico argenteus*, *A. furcifer*, *A. hensilli*, *A. luciocephalus* and *A. vitattus*. Studies showed that the incubation period in mosquitoes is approximately 10 days [22]. Zika virus can be transmitted through interpersonal sexual contact and can cross the placenta, affecting the unborn fetus. An infected mother (in the viremic stage) can transmit the virus to the newborn at the time of labor. [24][25][26]

The vertebrate hosts of the virus are the monkeys.

Figure 1: Aedes aegypti (http://www.cdc.gov)

Before the current pandemic, which began in 2007, Zika virus rarely generated collateral infections in humans, even in areas recognized as highly enzootic [7]. In 2009, Brian Foy, a biologist at Colorado State University, reported the sexual transmission of the Zika virus. [13][14]. In 2015, the Zika virus was detected in the amniotic fluid of two pregnant women, indicating that it is possible to cross the placenta and cause infections in newborns. [4][34][4][5][35][36]

DISEASE

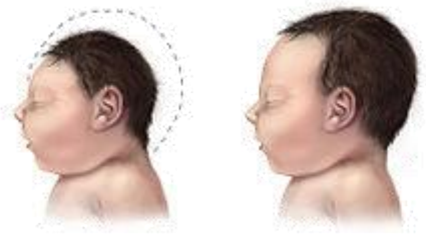
Zika virus infection symptoms normally include mild headache, maculopapular rash, fever, malaise, conjunctivitis and arthralgia. [33] The first thoroughly documented cases of Zika virus infections were described in 1964, being characterized by mild headache, progressing through maculopapular rash, fever and back pain. Within two or three days, the initial symptoms remitted, but the rash persisted. Patients with Zika fever are advised to rest and are prescribed fluids and acetaminophen, while aspirin and nonsteroidal anti-inflammatory drugs should be used only after Denga fever was ruled out, in order to reduce the risk of bleeding. [38]

COMPLICATIONS

Microcephaly. In December 2015, it was suspected that an infection of the fetus with Zika virus, transmitted transplacental, may cause microcephaly and brain damage. [5][34] Consequently, the European Centre for Disease Prevention and Control issued a comprehensive update on the possible association of the Zika virus with congenital microcephaly. [35] (Figure 2)

According to CDC Atlanta (Centers for Disease Control and PreventionUSA), "were reported cases of microcephaly defects in children of mothers who were infected with the Zika virus during pregnancy."

Figure 2. Comparison between a child with microcephaly (left) and a normal child (http://www.cdc.gov)



Zika viral infections were confirmed in several newborns with microcephaly; the number of microcephaly cases associated to Zika virus infection is unknown. [8][10][34]

On January 17, 2016 the Pan American Health Organization (PAHO), the Regional Office of the WHO, has recommended that its member states "establish and maintain the ability to detect and confirm cases of infection with Zika virus, given the increased number of congenital anomalies, Guillain-Barré syndrome and other neurological or autoimmune syndromes recorded in areas affected by Zika, to prepare healthcare facilities to respond to a possible increasing demand for specialized care for neurological syndromes and to strengthen prenatal care." [28][29]

DIAGNOSTIC

Zika virus is detected through PCR (gene amplification by Polymerase Chain Reaction). [15] [16] Since the viremic stage may be short, the WHO recommends that the RT-PCR testing should be done on the sera collected within 1 to 3 days after symptom onset or on the saliva or urine samples collected during the first 3 to 5 days after onset. [20][21][22][23]. Serological diagnosis can also be used by detection of specific IgM antibodies. Those appear towards the end of the first week of illness. [18]

Serological diagnosis can be difficult, given possible cross-reactions with other flaviviruses, for example the *Dengue* virus, *West Nile* virus or *Yellow Fever* virus. Zika commercial diagnostic tests are available at Euroimmun (www.euroimmun.com).

TREATMENT

Until present time, there is no specific antiviral treatment or vaccine available against Zika virus infection. The best form of prevention is to avoid mosquito bites.

Prophylaxis

The existence of mosquitoes and larval nests is an important risk factor for the infection with Zika virus. Disease prevention consists in decreasing the number of mosquitoes at source (elimination or modification of larval nests) and reducing contacts between these insects and humans. Those traveling to endemic areas should be informed on methods of protection against mosquito bites. These involve avoiding outdoor exposure at dusk and dawn, wearing clothes that cover as much exposed skin, using repellents, nets for beds impregnated with insecticide, accommodation in rooms with air conditioning and mosquito nets. It is also recommended emptying, cleaning and covering all containers that can collect water such as buckets, flower vases and tires in order to eliminate the places where mosquitoes can reproduce. During outbreak, health authorities can proceed to spray insecticide.

Vaccination

There are effective vaccines against several *Flaviviruses*. Vaccines against the *Yellow Fever* virus (antiamarilic), *Japanese encephalitis* and *Tick-Borneencephalitis* have been introduced from 1930, while the dengue fever vaccine just became available for use. [37]

According to Anthony Fauci, of the National Institute of Allergy and Infectious Diseases, attempts are made in order to obtain a Zika virus vaccine. [38] Researchers at the Research Center for Vaccines have extensive experience in obtaining vaccines against other viruses such as the Chikungunya and the Dengue fever virus. [38] Nikos Vasilakis, from the Center for Biodefense and Emerging Infectious Diseasesappreciated that getting the vaccine could take up to two years, but an effective vaccine for public use, approved by regulatory authorities, could be obtained in 10 – 12 years. [38][39][40][41]

EPIDEMIOLOGY

In 1947, scientists researching Yellow Fever revealed the onset of fever in a *Macaccus Rhesus* monkey located in a cage in the Zika Forest (Zika meaning "too high", in the Luganda language), near the Research Institute of Virology East Africa, in Entebbe, Uganda. The researchers have isolated from the monkey's serum a transmissible agent, which was first described in 1952 as the Zika virus [17] and was subsequently isolated in 1954 from a person in Nigeria. Since its discovery until 2007, rare cases of Zika virus infection were recorded in Africa and Southeast Asia. [40] In April 2007, the first outbreak outside Africa and Asia was declared on the island of Yap, in the Federated States of Micronesia; the cases were characterized by skin rash, conjunctivitis and pain, initially associated with Dengue, Chikungunya or Ross River disease. [41] However, the serum samples analyzed from patients in the acute phase of infection confirmed Zika virus infection. There have been 49 confirmed cases and 59 cases were disproved. There was no need for hospitalization and no deaths were reported. [42] Subsequently, outbreaks have appeared in Polynesia, Easter Island, the Cook Islands and New Caledonia. [5]

Starting April 2015, an epidemic broke out in Brazil with Zika virus (Figure 3) and has spread to South and Central America, the Caribbean, having a trend of global spread. In January 2016, CDC issued a level 2 travel alert for people traveling to affected areas (Table 1, Figure 4).

IMPLICATIONS FOR THE PUBLIC HEALTH

The WHO recommends that women planning to become pregnant should consult their physician before traveling to regions affected by the disease. [9][44] Governments and health agencies in the European Union, including UK and Ireland, as well as those in New Zealand, Canada, Colombia, Ecuador, El Salvador and Jamaica have issued similar travel warnings. Specific plans and measures were announced by authorities in Rio de Janeiro, Brazil, to prevent the spread of the Zika virus during the Olympic Games, taking place in this city, in 2016. [11][45][46]

According to CDC, Brazilian health authorities have reported more than 3,500 cases of microcephaly between October 2015 and January 2016. Some affected infants had a severe type of microcephaly, while others died.

These manifestations may be associated with Zika infection, occurred during pregnancy. Several studies are planned to assess the risks of the Zika virus infection during pregnancy. [45] In the worst affected regions in Brazil, about 1% of newborns are at risk for microcephaly. [46]

COMMENT

In humans, Zika virus causes an infectious disease called Zika fever, characterized by fever, headache, maculopapular rash, malaise, conjunctivitis, arthralgia etc.

The WHO has warned that the spread of Zika virus, transmitted by mosquitoes, is ''a global public health emergency'' and can be correlated with an increased number of newborns with congenital malformation recorded in Brazil last year.

WHO warns that Zika virus, transmitted mainly by mosquitoes, "explosively" spreads in South America, where in 2016 could be millions of cases. The priority is to protect pregnant women and to control the mosquito populations.

Medical experts are concerned about the very rapid transmission, over long distances of the virus with devastating consequences. From the confirmation of the presence of Zika virus, in May 2015, the virus has spread so far in 23 countries, including Brazil, Bolivia, Paraguay, Mexico, Venezuela and the epidemic continues to spread.

CONCLUSIONS

The World Health Organization has warned that the spread of Zika virus, transmitted by mosquitoes, is a

”global public health emergency”, which can be correlated with the increased number of newborns with congenital malformation recorded in Brazil last year and that the virus "explosively" spreads in South America, where in 2016 could be millions of cases.

Experts are concerned about the very rapid transmission, over long distances of the virus; the consequences can be devastating, and the priority is to protect pregnant women and to control the mosquito populations.

National health authorities are requested to take necessary measures for the prevention, diagnosis and treatment of Zika fever cases and to isolate import cases, in order to impede the spread of the disease.

Also, scientific research is needed in order to obtain an effective vaccine against Zika virus.

Morphopatological and histochemical highlights in normal and varicose vein wall

Alina Condor[1], Caius Solovan[2], Liliana Vasile[2]

Abstract: *The nutrition of the venous wall appears to be an important factor in the vascular-fibrillar trophicity and in the dynamic of the extracellular matrix formation for the normal veins and, for the chronic venous ulcers of legs, on period of healing. Sequential biopsies were taken at various levels of venous wall of external and internal saphena in 16 cases presenting a chronic condition of legs venous system (35-58 years old patients, both sexes). 8 vein fragments with normal macroscopic appearance were also taken, in necropsy.*

These samples were analyzed using regular morphological methods and some histochemical reactions to reveal the glycogen, glycoproteins, and glycosaminoglycans substrates. There were been used the Gomori silver impregnation and orcein to expose some specific substrates like reticulin or elastin. Other staining methods, like Gomori trichrome, were used to differentiate the specific structures of the vein wall, were used to differentiate the specific structures of the vein wall.

A rich vascularization of normal and dilated vein wall could be remarked.Angiogenesis in vein wall and vasa vasorum changes as well as alcianophilic of vascular intima seem to be reactive and protective factors, depending on the applied therapeutic modalities. The veins are weak structures whose integrity depends on the thickness of the media and the support of neighboring structures.

INTRODUCTION

The emergence of varicosities it is supposed to be a consequence of defective development of venous wall and appears to be inherited. The proper nourishment of the venous walls appears to be an important factor in their trophicity. The incidence of varicose veins is about 1% of the adult population [5]. Both obesity and aging are involved as risk factors for emergence of defects in venous wall tissue support. The etiology and pathophysiology of varicose disease remains controversial. We emphasize the involvement of the following lesional links amid stasis hypoxia:

- Redistribution of microcirculation with arrangement in lobular aggregate of vessels in the superficial dermis;

- Areas of floride proliferation mimicking Kaposi's sarcoma (acro-angio-dermatitis), reticular dermis fibrosis and massive deposits of hemosiderin, degeneration of dermal fibroblasts (senescent fibroblasts converted by modulation into myofibroblasts having a role in periulceros tegument retraction) to extended tissue matrix lysis;

---

[1] Department of Dermatology, Emergency Military Hospital, Timișoara, Romania
[2] Victor BabeșUniversity of Medicine and Pharmacy, Faculty of Medicine, Timișoara

-Outbreaks of fat necrosis concomitant with a proliferative-alternative response of adjacent epidermal, hyper parakeratosis and orthokeratosis and pseudoepitheliomatous hyperplasia.

The presence of lytic degradative tisular factors (metalloproteinase) and activation of monocito-macrofagic system induced degradation of the basal membrane and chronic venous ulcers.

Morpho-histochemical current study aims to deepen the importance of veins wall nutrition in normal and dilated veins. It also envisages the re-active participation of supra-adjacent dermo-epidermal tissue, the possible influence on vessel permeability and vasoprotective or anticoagulant medication used in selected cases in the study.

MATERIALS AND METHODS

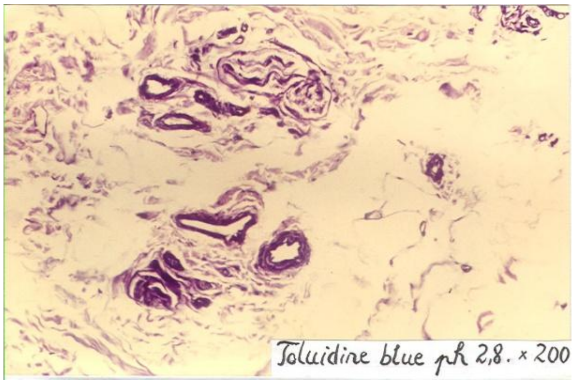
16 biopsies were taken sequentially from the varicose saphenous in areas of dilated vein (12 cases) and in the vicinity of shank chronic venous ulcer (4 cases); Saphenous fragments from normal vein were collected at necropsy (8 cases). Cases have included both sexes. The selected cases were with at least 5 years of disease duration and the type of treatment was also considered.

Patients in the study were selected from the inmates in Department of Surgery of Military Emergency Hospital and University Clinic of Dermatology in Timisoara.

Processing of samples was performed at the Department of Histology of Medicine and Pharmacy University in Timisoara by usual histological techniques: all samples were fixed in 10% formalin, buffered formalin, AFA fixator (Alcohol - Formaline - Acetic acid), paraffin inclusionated, sectioned at 5 µm, then colored by hematoxylin-eosin. For histochemical study, there were been applied reactions PAS (blue Alcian (BA)) and salivary amylase-PAS (Alcian blue used at pH 2.8 and pH 0.5); blue toluidine (BT) at pH 5 and pH 2.8; it was used Gomori silver impregnation for reticulin and it was also used trichrome Gomori reaction.

Orcein staining method was used to expose elastin.

Figure 1: Lipodermatosclerosis (*toluidine blue, pH 2,8, ×200*)

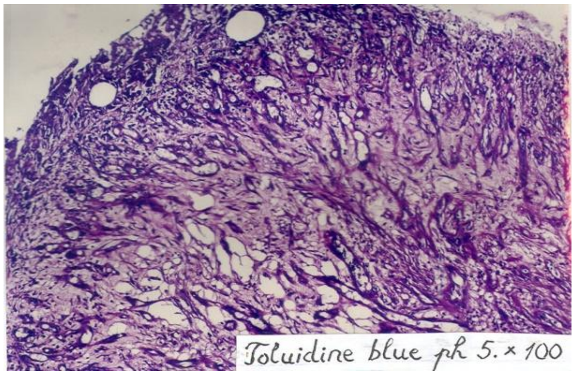


RESULTS

In all examined cases, the wall of external and internal saphenous veins was well vascularized, containing arterioles, venules, capillaries in musculo-fiber media. Constant, parietal capillaries from vasa vasorum were not flattened. In varicose veins adventitia, in small and medium vessels, were frequently found leukocytic marginations and acidophilic deposits and PAS positive, weak metachromatic fibrin (Figure 1).

Fibrin sleeves were also observed in the wall vessels of varicose veins in which angiogenesis is very marked. For AT, were remarked weak metachromatic perivascular sheaths, at pH 5 and chromophobe tissue matrix of dilated veins sheaths, at pH 2.8. Orthochromatic of nuclei allows observing the phenomenon of leukocytes margination (mostly lymphocytes) in the parietal small and medium vessels up next to intima, for both pH used (Figure 2).

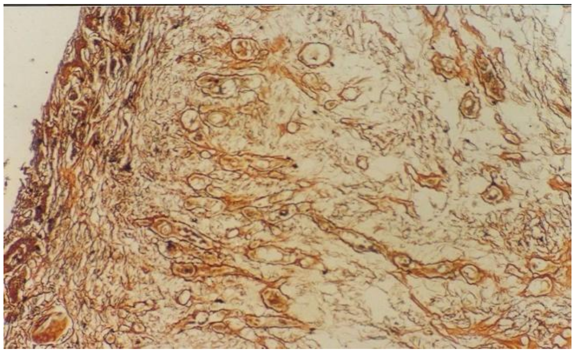
Figure 2: Perivascular sheaths and parietal leucocytes margination in small and medium sized vessels, close to venous intima (*toluidine blue, pH 5, ×100*)



In all methods used in this study, the average media of varicose veins appears thickened through a rich smooth muscle proliferation (HE col., Gomori trichrome col.), with weak orceinic material fragmented through the wall layers (Orcein col.). There were observed fake elastic limitations, fragmented, disorganized (orcein, Gomori trichrome). In one case of all cases examined, using combined staining AA-PAS, which stands under anticoagulant therapy, an edemic intima and hyperplasia were observed, with fundamental alcianophilic substance (FS) and somewhere with deposits PAS positive as a rich interstitial material PAS positive all that pushing aside and cleaving muscle layers of the vascular media. Other intimal changes reported in our study are notches and extensive fibrosis, miointima hyperplasia of saphenous varicose veins.

Alcianophilic fibrillar material with reticular disposition is perivascular distinguished in the neo-capillaries that invade from adventitia media. Silver impregnation for reticulin (Figure 3) shows neo-formation basic membrane by budding vasa vasorum from adventitia to media to decline to extinction the reticulin network of media muscular interstice and vasa vasorum walls.

Figure 3. Reactive angiogenesis in variceal venous wall (*silver impregnation, ×200*)



The phenomenon seems to affect 2/3 of external walls of the dilated veins. In neighboring dermal and epidermal tissue and in the perivascular support appear lesions like: lipodermatosclerosis, fibrosis and perivascular fibrin deposits and interstitial fragmentation of elastic fibers in the deep of dermis, tinctorial variations of epidermal cells cytoplasm for which an accumulation of PAS positive material could be noted and cemented SF was PAS reactive. For silver impregnation, the dermal epidermal limit appears fibrillary fine, thinner than the normal appearance.

DISCUSSIONS

The changes of vein wall tissue architectural pattern take place simultaneously with the progression of venous distension in varicose vein disease. It is noticed an important reaction of vessels in vasa vasorum which angiomatosic proliferate, invading media, almost to intima, leading to muscular media hypertrophy [5]. Vascular proliferation can be reactive to miointima hyperplasia and to varicose wall media. Chronic shank venous ulcer it is possible to occur, in time.

Thus, as a reaction to increased venous pressure in a vein much thickened, on account of media and intima and hence to the shank edema, fibrin sleeves occur, those may inhibit the angiogenesis [4]. However, it is created a protection against increased venous additional pressure with a possible role in causing tisular ischemia [6][8].

Fibrin sleeves were found around the capillaries of the dermis in lipodermatosclerosis. Massive deposits of fibrin are involved in elastin fragmentation of the deep dermis and in elastic limitations of vascular walls. Vasa vasorum angiomatosis proliferate in invading varicose vein media. Since 1992, "leukocyte sleeve" was reported as a response to chronic stasis. White blood cells can accumulate in the lumen of capillary and venular, increasing perivascular resistance.

Activated endothelium becomes thrombogenic surface (via tissue factor secreted by endotheliocyte: factor VIIa, factor X-Xa). Simultaneously, activated endotheliocyte was involved in angiogenic peptide synthesis, stimulating neovascularization of dermis and ectasiated venous walls. Tissue anoxia and ulceration is installed.

Consistent with the cited literature, we found also an increased number of capillaries in the skin of patients with venous hypertension in the lower limbs.

Wall vessels are the only ones bringing oxygenated blood, draining interstitial fluid and extravasated colloidal material [7][1][3]. This explains the rapid drainage and metastasis of tumor cells via veins and lymphatics with rich vascularity, having intraparietal capillaries opened.

Adventitial enriched positive PAS material, periadventitial and intraparietal, is represented by fibrin, and also by a macromolecular glycoprotein substrate containing laminin, fibronectin, tenascin detected by immunocytochemical investigations by some cited authors [2][5].

So we can correlate the "leukocytic margination" phenomenon in vasa vasorum and intraparietal vessels with depolymerization of SF tissue more evident in the 2/3 of external portion of the varicose venous wall.

The histochemical reactions used in our study, draw attention to the changes in the three fibrillar component. In varicose veins (dilated segments thereof) we found a quantitative increase of mature collagen fibers and reticulin, morpho-histochemical revealed, with a decrease and fragmentation of elastic fibers in the dilated walls. Together with the degradation of elastin, reticulin network growth can be an important factor in the parietal frailty in shank venous insufficiency evolution.

Marked alcianophilia of intima (AA pH 2.8) calls attention to presence at this level of complex carbohydrates with carboxyl groups and hydroxyl radicals in position of vic-glycol (sialic acid and hyaluronic acid) which act as intima hydrator, but may decrease macromolecular complexes stability of glycoproteins (with increase of sialic acid amount).

Sialic acid carboxyl groups and other substances not yet identified are responsible for basophilia and metacromazia of certain reticulin networks and basement membranes. The enriched PAS positive interstitial material in dilated vessels media is favorable to reticulin collagenization (gradual multiplication of preexistent collagen fibers in a glycoprotein matrix apparently unchanged).

Reticulin collagenization occurs when the hydroxyl group probably belonging to hydroxyproline and hydroxylysine achieve the appropriate concentration [9].

In the cases we investigated, collagenization is conducted in a glycoprotein reticulin dominant matrix (in the external 2/3 dilated vein wall), progressively decreasing toward intima, simultaneously decreasing nourishment intake by vessels of the vein wall fibrosing.

CONCLUSIONS

Morpho-histochemical methods draw attention to the complex of walls reshuffles of venous leg during chronic venous insufficiency. There are being considered the three coats of veins in that appear to be successive lesional patterns: mio-intimal hyperplasia, medial muscle hypertrophy, reactive angiogenesis, lipodermatosclerosis, collagenization of medial muscle.

The chronic venous stasis can be quantified by morphological parameters: mio-intimal hyperplasia, medial muscle hypertrophy, reactive angiogenesis, lipodermatosclerosis, collagenization of medial muscle. The prolonged venous hypertension modifies both the local microcirculation conditions and selecting of fibril-forming cells, triggering the evolution of chronic venous ulcers.

Expandable stents in digestive pathology – present use in an emergency hospital

Mădălina Ilie[1], Vasile Șandru[1], Cristian Nedelcu[1], Bogdan Popa[1], Gabriel Constantinescu[1]

Abstract: *Introduction: Self expandable metal stents (SEMS) are developed lately, as an effective and safe, less invasive alternative of surgery for the treatment of malignant intestinal/biliary obstruction. Recently, SEMS are also introduced in benign pathology.*

Aim: The aim of this presentation is to report a retrospective analysis of the total number of SEMS placed for esophageal, enteral, colorectal and biliary obstruction during the last 3 years in Clinical Emergency Hospital Bucharest, as well to review the literature published on this issue.

Methods: Between 2013-2015 in Clinical Emergency Hospital Bucharest, we have placed: 232 esophageal stents, 23 enteral stents, 5 colonic stents and 75 biliary stents under radiologic guidance. The main parameters followed were represented by: sex, age, grades of obstruction, stent diameter and type, immediate and late complications and survival rate.

Results: Regarding the esophageal stenting, most of the indications were malignant obstruction (155 cases of esophageal cancer and 30 cases of extrinsic compression), but also for esophageal fistula, peptic stenosis and even traumatic esophageal rupture. The majority of the enteral and colonic stents were inserted for malignant obstructions, having only 2 cases with benign obstructions. This is also the case for biliary stenting, were most of the indications were represented by pancreatic cancer. Technical and clinical success rates were approximately 92% and 80%, respectively. There were no major complications of perforation, bleeding, or death.

Conclusions: SEMS insertion can be performed safely, with minimal complications and hospitalization allowing the restart of oral feeding and improvement of nutritional status for the digestive obstruction or jaundice disappearance in case of biliary obstruction. It represents the first option for unresectable digestive/biliary malignant obstruction.

Keywords: *expandable stents, malignant obstruction, fistula, stenosis.*

INTRODUCTION

Over the past decades, the endoscopic approach for palliation of malignant obstruction has overcome the use of percutaneous approach. The options for endoscopic stenting are either self-expandable metal stents (SEMS) or plastic stents (PS). PSs are composed of polyethylene, polyurethane, or Teflon,whereas SEMSs are made of various metal alloys that are constructed to achieve adequate radial expandable force without sacrificing flexibility and conformability to the duct [1].SEMSs can be either uncovered or covered with material to prevent tumour ingrowths. Recently, uncovered self-expandable biodegradable stents were added to this portfolio [2].

The ideal stent have to be pliable, atraumatic but also forceful to maintain patency and position in the lumen. However, stents should also be easily removable and without any risk for benign hyperplastic or malignant tumor ingrowths or overgrowth.

---

[1] Clinical Emergency Hospital Bucharest

The current guidelines from the American Society for Gastrointestinal Endoscopyfor distal malignant biliary obstruction recommend either SEMSs or PSs, with PSs preferred in cases of distant metastasis and short life expectancy. However, studies have shown that although PSs are less expensive, metal stents have better drainage and longer patency,with recent data showing they are more cost-effective [3][4].

METHODS

We have done a retrospective, non-randomized study between 2013-2015 in Clinical Emergency Hospital Bucharest. We have placed: 232 esophageal stents, 23 enteral stents, 5 colonic stents and 75 biliary stents under radiologic guidance. The main parameters followed were represented by: sex, age, grades of obstruction, stent diameter and type, immediate and late complications and survival rate. We had exclusion criteria: an INR more than 3 and an estimated survival time less than 3 weeks. Regarding the dysphagia we have used Mellow and Pinkas's scale.

0 = able to eat normal diet / no dysphagia.
1 = able to swallow some solid foods
2 = able to swallow only semi solid foods
3 = able to swallow liquids only
4 = unable to swallow anything / total dysphagia

We have used most the nitinol stents (alloy of nickel and titanium), because of their ability to conform to anatomical angulations and the latter for their removability.

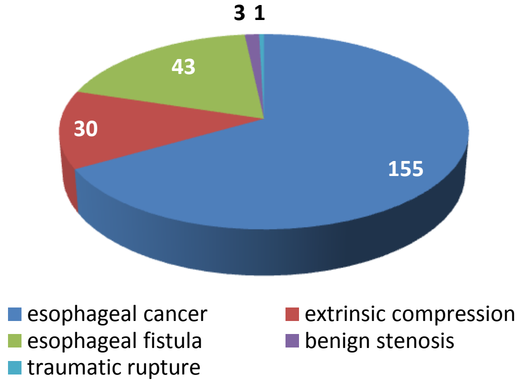
RESULTS

More than 65% of the patients were male with age varying between 49 and 83 years old.

Regarding the esophageal stenting we have placed in Clinical Emergency Hospital Bucharest, 232 oesophageal stents for the following indications (Figure 1):

-155 cases of esophageal cancer
-30 cases of extrinsic compression
-43 cases of esophageal fistula
- 3 cases of benign stenosis
- 1 case of traumatic rupture of the esophageal wall

Figure 1: Graphic representation of esophageal stenting indications



The majority of the cases (> 50 %) have unresectable disease at the time of diagnosis, either because of distant metastases or unsuitable candidates for surgical resection.

The aims of palliative therapy are to ameliorate symptoms of dysphagia, treat complications, maintain oral intake, minimize hospital stay, relieve pain and ultimately improve their quality of life.

We have used: totally covered SEMS or partially covered SEMS. Fully covered stents are more prone to stent migration; removable and theoretically may be more suitable for benign strictures/fistula whereas partially covered stents have a small portion of exposed bare metal in both proximal and distal ends to allow embedding into the oesophageal wall, which helps to decrease stent migration. The uncovered portion of the partially covered stents allows embedding and anchoring. No differences in survival rates were observed between these two types [5].

The techniques used for inserting the stent were: OTG – over the guidewire (most of the cases) or TTS (through the stent) both under radiologic view. At the beginning the lesion is visualized under endoscopy (Figure 2A – oesophageal fistula) and upper end is marked by injection of contrast agent into the submucosa (Figure 2B).

It is very important for the marking to be done internally and not to put external marks that may move during the procedure. The stents are mounted in a preloaded constrained position on a delivery catheter.

A guide wire is passed through the lumen of the catheter (Figure 2C), and when the wire has been advanced beyond the obstruction, the stent is passed over it and positioned across the stricture with the upper end at the position of the internal contrast mark (Figure 2 D, E, F).

Figure 2A: Esophageal fistula

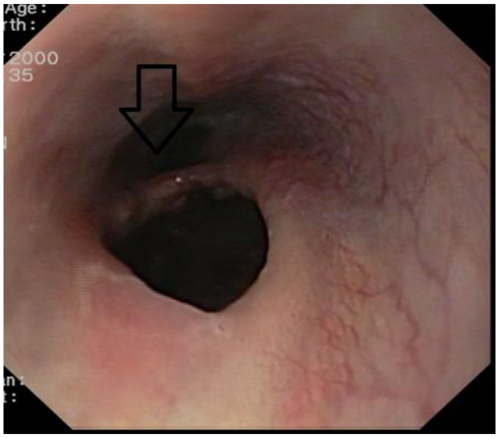


Figure 2B: Contrast injection

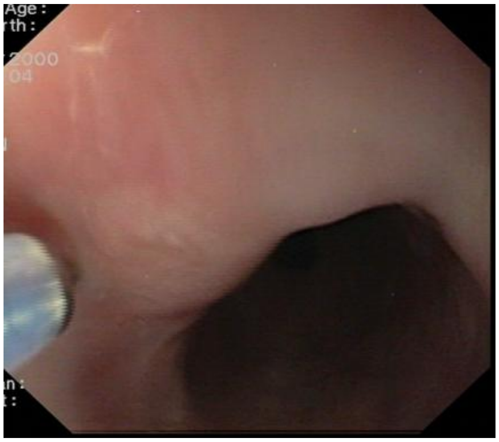

The immediate complications encountered were: retrosternal pain (60%), alleviated after antalgics, stent migration while as late complications we had: food impactation (7%),fibrous tissue invasion (4%), tumoral invasion (5%),uncovered fistula and upper GI bleeding.

Figure 2C: Guidewire insertion

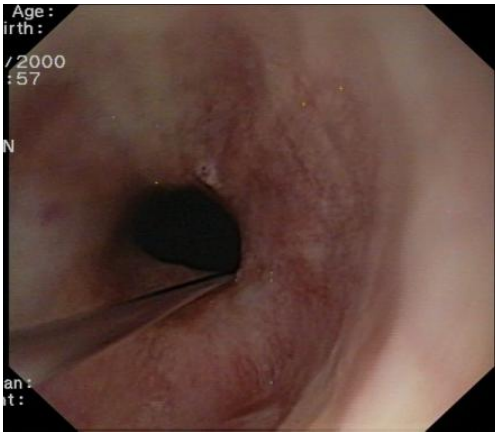

Figure 2D: Stent deployment

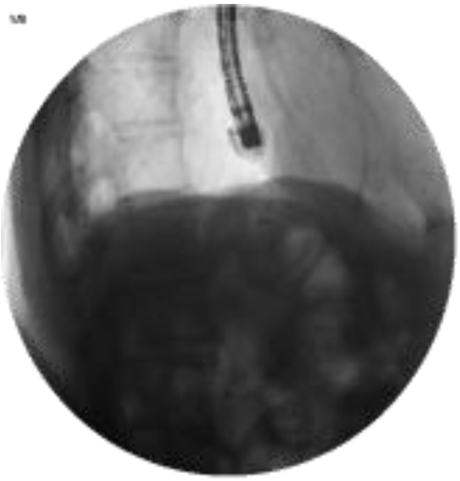

Figure 2E: Stent view on RX

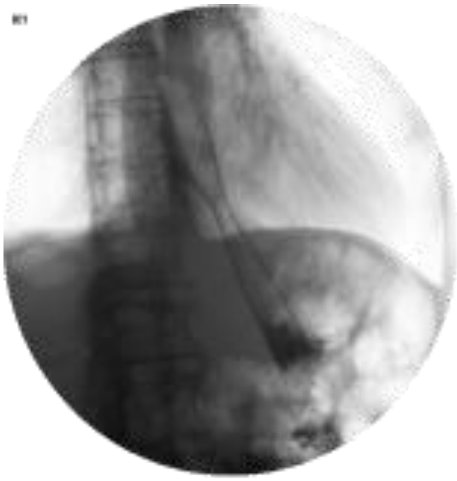
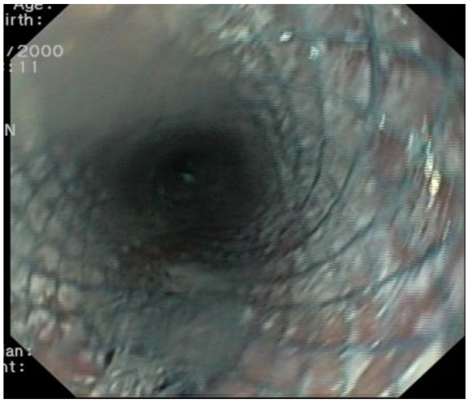


Regarding the enteral stenting we had 23 total cases: 21 for malignant extrinsic compression and 2 cases for benign stenosis. The technique used was TTS (through the scope) with low rate of complications.

Figure 2F: Stent under endoscopy view



A specific situation was double stenting, both enteral and biliary (Figure 3 A, B), especially in pancreatic head malignancies with obstructive components.

Figure 3A: Double stenting (enteral+biliary)

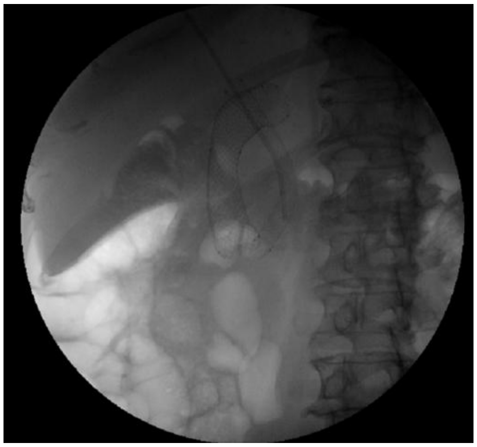


Figure 3B: Enteral stent-endoscopic view

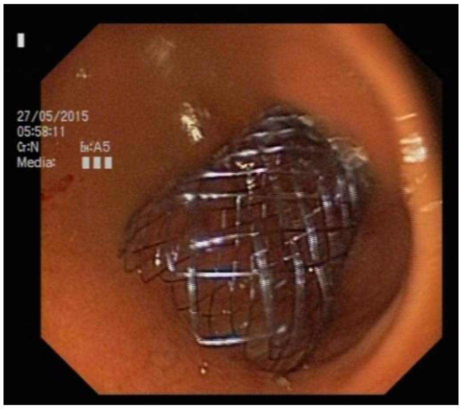
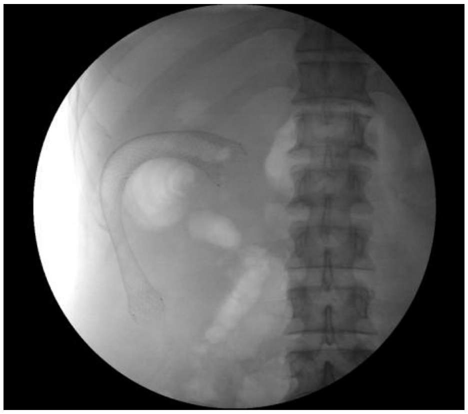


Colonic SEMS placement is recommended as the preferred treatment for palliation of malignant colonic obstruction, except in patients treated or considered for treatment with antiangiogenic drugs [6]. Stent insertion may be considered as an alternative to emergency surgery in those who have an increased risk of postoperative mortality. We have placed only 5 colonic stents (Figure 4), mainly because of ease of accessibility to the surgical service in our hospital.

Figure 4: Colonic stent



In case of biliary stenting we have inserted 73 stents for malignant obstruction (approx. 60% pancreatic cancer) and only 2 for benign obstruction (chronic pancreatitis). SEMSs range from 4 to 12 cm in length with diameters when expanded ranging from 6 to 10 mm.

Self-expanding metal stents (SEMSs) are built from different metal alloys, mainly nitinol, that are used to achieve adequate radial expansive force leading to increased patency duration and reduced recurrent obstruction.

SEMSs are preloaded in an outer sheath with a diameter of 8.5F or smaller, allowing use with a therapeutic duodenoscope. After placement in the duct, the outer sheath is withdrawn, allowing the stent to expand (Figures 5A, B, C).

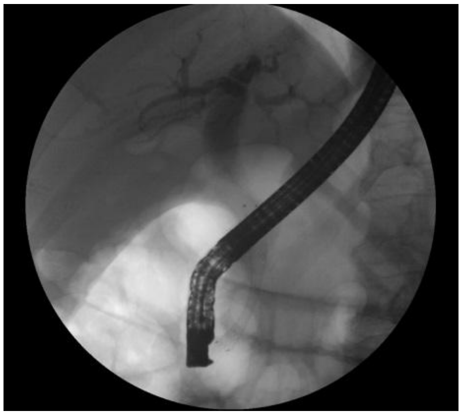
SEMSs can be covered, partially covered, or uncovered.

Partially or totally covered SEMSs can be repositioned or fully removed, reduce the rate of stent occlusion but they have risk of cholecystitis because of involvement of the cystic duct orifice). Acute cholecystitis may occur in as many as 10% of patients with intact gallbladders after placement of a covered SEMS across the cystic duct. In opposition, uncovered SEMS migrate less but have risk of tumor ingrowths [3].

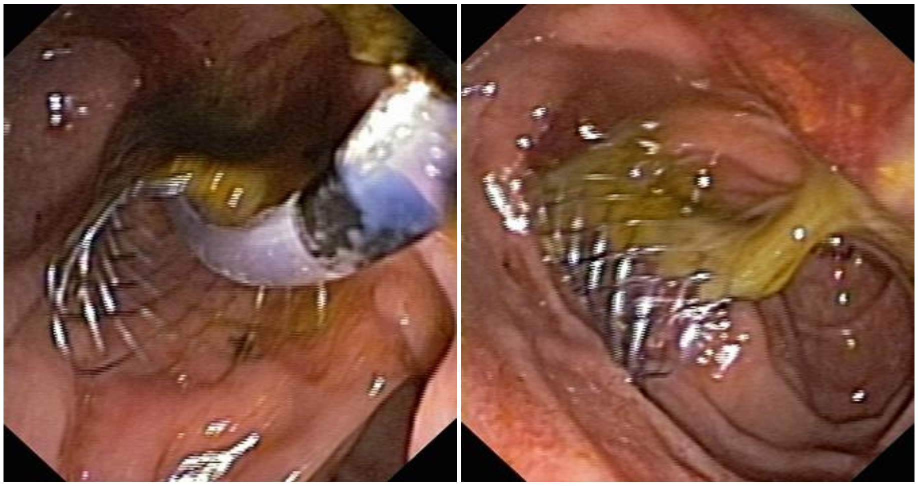
SEMS insertion at patients with malignant biliary obstruction palliate jaundice, anorexia and most important help the initiation of chemotherapy that otherwise would be contraindicated.

Initial insertion of a plastic stent is most cost-effective if patient life expectancy is shorter than 4 months; if it is longer than 4 months then initial insertion of a SEMS is more cost-effective.

Figure 5A: Distal biliary obstruction; stent insertion radiologic view



Figures 5B, 5C: Endoscopic views



CONCLUSIONS

SEMS represents a very useful alterative, with minimal complications to classic surgery for palliation of unresectable digestive/biliary malignant obstruction. With the current development and applications of new materials and technologies, the future of stenting is evolving.

New trends include drug-eluting stents, biodegradable biliary/esophageal stent and the use of biodegradable polymers for local drug delivery, having also curative aim [7] . Radiation therapy, a cornerstone of treatment for malignant disease of the esophagus, may also be administered in conjunction with placement of esophageal endoprosthetics [8].

Regarding the biliary malignant obstruction, we recommend that SEMSs should be the first option because they have better patency, a lower occlusion rate, less need for reintervention, and fewer adverse events than plastic stents.

In conclusion, expandable metal stent placement is a very effective way of re-establishing luminal patency with negligible complications for an expert endoscopist.

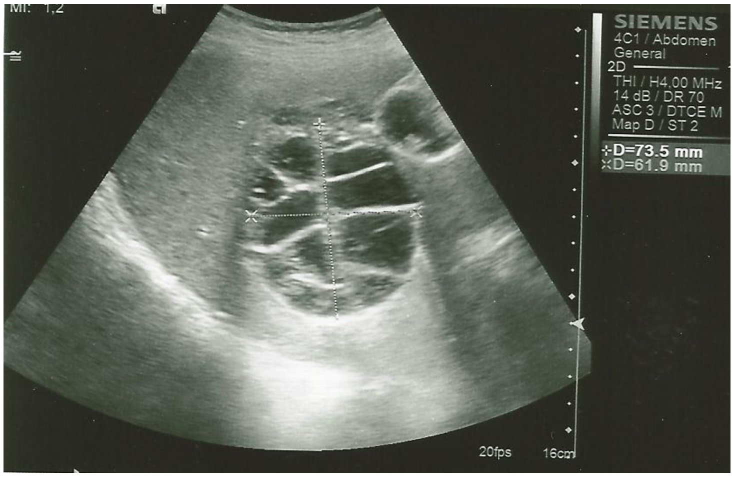
Hepatic hydatid cysts

Cătălina Diaconu[1], Mădălina Ilie[2,3], Alexandru L. Chiotoroiu[3], Laura Voicu[1], Daniel O. Costache[1], Raluca S. Costache[1,2]



43 years old man presented with recently installed abdominal pain localized in the hypocondrium and epigastrium associated with jaundice and pruritus.

The patient's history included operated bilateral inguinal hernia. Physical examination yielded jaundice, normal aspect of postoperative scars in the inguinal fossae (left and right), pain in the hypocondrium and epigastrium, no guarding, rebound or bruits were found.

Laboratory findings reveal leukocytosis with eosinophilia, hepatic cytolisis (alanine aminotransferase = 219 U/L), hyperbilirubinemia with a higher conjugated bilirubin (total bilirubin=6.01mg/dL, conjugated bilirubin=4.7mg/dL).

Ultrasonography reveals a round transonic image of 7/6cm localized in the IV and VIII segment, with septa that suggests liver hydatid cyst, hyperechoic image of 9mm (hydatid cyst) and a 9mm gallbladder polyp. Computed tomography shows hepatomegaly with a cystic multiseptate image in the IVth segment of 8.5 cm.

Under treatment against pain, proton pump inhibitor, hydratation and regime during hospitalization the symptoms disappear. However the hepatic cytolysis worsens with the progressive growth of alanine aminotransferase to values of 916 U/L, hence antihelminthic treatment is delayed.

Enchinococcal infection caused by the larval form of *Echinococcus granulosus* remains an important health issue worldwide. Hepatic hydatid cyst is the most frequently encountered form (50-93% of the cases) and left untreated these grow and lead to: developing fistulae in adjacent organs, rupture in the peritoneal cavity, produce daughter cysts or dye (rarely)[1]. Clinical manifestations appear after the cyst is larger than 10cm in diameter and only a third of the patients experience symptoms.

Even though biological finding are nonspecific, elevated bilirubin and alkaline phosphatase may appear. Leukocytosis may appear due to infection of the cyst and eosinophilia is present only in a quarter

---

[2] Carol Davila University of Medicine and Pharmacy, Bucharest
[3] Floreasca Emergency Hospital, Bucharest

of patients [2].

Despite the fact that ultrasonography remains the main pillar in the diagnosis of the disease, computed tomography and serology help improve the accuracy of diagnosing liver hydatidosis. WHO Ultrasound classification of echinococcal cysts helps establish the treatment: 1 (unilocular, anechoic cyst with double line sign), 2 (multiseptate honey comb cyst), 3a (cyst with detached membranes), 3b (cyst with daughter cysts in solid matrix), 4 (heterogenous contents and no daughter cysts) and 5 (solid plus calcified wall). CE4 and 5 are inactive.

On the other hand Gharbi classification also divides in 5 types: type I cysts consist of pure fluid; type II has a fluid collection with a split wall; type III cysts contain daughter cysts (with or without degenerated solid material); type IV has a heterogeneous echo pattern; and type V has a calcified wall. Therefore our case presents a hepatic hydatid cyst stage CE2 after WHO classification and type III after Gharbi classification.

Uncomplicated and small lesions (under 5cm) CE1,2 and 3 can be treated with oral albendazole (10-15mg/kg/day) and close monitoring. However, large CE1 and CE3 cysts need treatment with both albendazole and PAIR (percutaneous aspiration, introduction of scolicide and reaspiration), performed after initiation of albendazole.

Primary surgical treatment has been replaced with less invasive methods since the relapse rate can reach 20%. In patients with complicated cysts, surgery is the treatment of choice. CE4 and 5 only need to be monitored [1][3].

More than simple hepatic cysts

Daniela Tabacelia[1], Mădălina Ilie[1], Alina Constantin[1], Anca Macovei Oprescu[2], Gabriel Constantinescu[1]

Abstract: *Caroli diseaseis a rare congenital disorder that classically causes saccular dilatation of the bile ducts. The complications of Caroli include choledochal cysts with recurrent cholangitis, abscess formation, septicaemia, intrahepatic lithiasis and amyloidosis.We report a rare case of a young female with Caroli disease pointing out the intrahepatic lithiasis as a rare complication of the disease.*

Learning points

- *Caroli disease is an uncommon condition that should be considered in the differential diagnosis of hepatic essential cysts.*
- *Clinically, it is characterized of recurrent episodes of fever and pain.*

The correct and early diagnostic is important because of the different complications and treatment unlike the essential hepatic cysts.

Keywords: *Caroli disease, intrahepatic lithiasis, endoscopic retrograde cholangiopancreatography*.

CASE REPORT

A 28 years old female presented to the emergency department with abdominal pain and fever after an ERCP procedure performed 2 weeks ago. From her disease history we retain an acute pancreatitis that was classified Balthazar B, one year ago, assumed to be caused by biliary main duct lithiasis; at that moment her initial biology showed ASAT 156U/L, ALAT 126U/L, lipase 2,398U/L, bilirubin 32 mmol/l and white cells 14,590/mmc; there was no sign of complication (acute cholangitis) that would have required a surgical treatment in emergency. Her family history was inconclusive for any specific digestive condition.

In our hospital, on physical examination her body temperature was reaching 38^0C, the heart rate 110 bpm, and blood pressure 110/70mmHg; on palpation she presented mild tenderness on epigastric and right quadrant; the usual blood tests showed white cell count with neutrophils raised, hepatic cytolysis and cholestasis until 5 times normal value. Next step was performing an abdominal ultrasound which revealed hepatic cysts (dilation of intrahepatic bile ducts) with liver hyperechoic images with acoustic shadow suggestive of intrahepatic lithiasis (Figures 1 A and B). A CT scan and a MRI were performed and revealed a normal pancreas without Wirsung dilatation, the biliary main duct with a 7 mm diameter without stones inside, and normal gall bladder without signs of cholecystitis but with beaded intrahepatic biliary duct dilatation until 18

---

[1] Department of Gastroenterology, Clinical Emergency Hospital Bucharest
[2] Department of Gastroenterology, Agrippa Ionescu Hospital

mm alternated with normal caliber ducts with numerous images of stones inside with a 12 mm maxim diameter. The dilated biliary canaliculi wall presented signs of cholangitis. All clinical and paraclinical data were typical for a Caroli disease with intrahepatic lithiasis and secondary cholangitis. The patient received treatment with urso-deoxy cholic acid (UDCA), antibiotics, anti-inflammatory drugs and pain medication followed by the resolution of the inflammatory episode.

Figure 1A

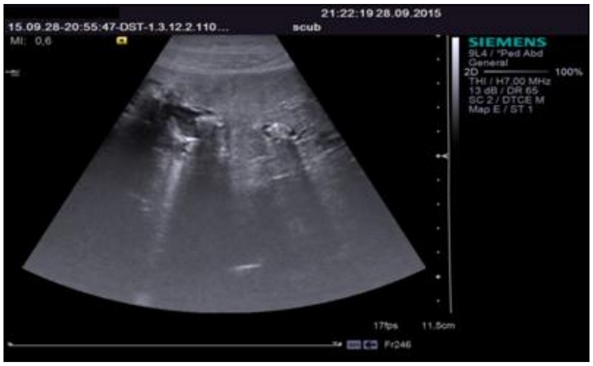

Figure 1B: Abdominal ultrasound revealing hepatic cysts with intrahepatic lithiasis

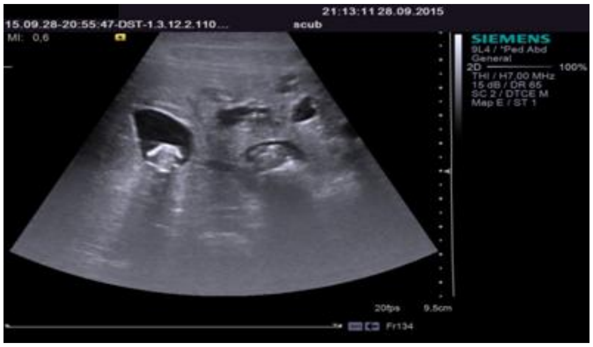

DISCUSSION

The hallmark of Caroli disease is intrahepatic duct dilatation [1]. Patients with Caroli disease are usually presenting to the hospital, when they develop complications as the result of biliary stasis, which leads to stone formation and infection. The stones are brown pigmented stones, composed of inspissated bile[1].

Caroli disease has two forms, one associated with congenital hepatic fibrosis and a simpler form occurring alone. The former, called Caroli's syndrome is associated with portal hypertension, and it's complications including splenomegaly, hematemesis and melena. Caroli disease is also associated with liver failure and polycystic kidney disease. The cause appears to be genetic; the simple form is an autosomal dominant trait while the complex form is an autosomal recessive trait.[2] Females are more prone to Caroli disease than males.[2] Family history may include kidney and liver disease due to the link between Caroli Disease and ARPKD (Autosomal recessive polycystic kidney disease). The symptoms include fever, intermittent abdominal pain, and hepatomegaly. Occasionally jaundice occurs.[3] Laboratory tests indicate cholestasis and hepatocytolysis associated with an inflammatory syndrome in the acute stages.

Caroli disease usually occurs in the presence of other diseases, such as autosomal recessive polycystic kidney disease, cholangitis, gallstones, biliary abscess, septicemia, liver cirrhosis, renal failure, and cholangiocarcinoma (7% affected).[2] People with Caroli disease are 100 times more at risk for cholangiocarcinoma than the general population.[3] Modern imaging techniques allow the diagnosis to be made more easily and without invasive imaging of the biliary tree.[4] Abdominal ultrasound can detect saccular or fusiform dilation of the bile ducts. Images taken by CT-scan or MRI will show enlarged intrahepatic (in the liver) bile ducts due to ectasia; cholangiography is the best approach to show the enlarged bile ducts as a result of Caroli disease.

The treatment of Caroli's disease depends on the clinical features and the location of the biliary abnormalities. Cholangitis is treated with appropriate antibiotics. In case of intrahepatic cholelithiasis litholytic therapy with urso-deoxy cholic acid (UDCA) is indicated[5]. When the ductal abnormalities are localized to one lobe, lobectomy relieves symptoms and appears to remove the risk of malignancy. In case of diffuse involvements of both lobes of liver, treatment options include conservative management, endoscopic therapy (sphincterotomy for clearance of intra-hepatic stone), internal biliary bypass procedures and in carefully selected cases liver transplantation[5].

Nutritional approach in late gastric stenosis after gastric sleeve

Adina Mazilu[1]

INTRODUCTION

Laparoscopic gastric sleeve(LGS) is a very frequent used procedure nowadays in Romania, with more than 100,000 reported patients operated until now, the most part of patients being operated in private settings. It is a simple and efficient procedure, less expensive than gastric by-pass, with fewer complications, but can reduce obesity complications almost as well as gastric by-pass. Indications for this type of surgery are:

- Body Mass Index is greater than 40 kg/m^2 or between 35-40 kg/m^2 and patient has significant pathology that may benefit from weight loss-like diabetes, hypertension
- Severe co morbidities (cardiac, pulmonary, liver disease)
- Advanced age at time of operation
- Inflammatory bowel disease (Crohn's disease)
- Patient uses chronic medications (anti-inflammatory or immunosupressive)
- Need for continued surveillance of the stomach (that couldn't be evaluated after a gastric bypass)
- Severely enlarged liver found during the operation
- Severe adhesions or scarring to the bowel found during the operation
- Any combination of the above that significantly increases the patient's anesthetic or surgical risk

LGS may be used also combined with gastric by-pass done at 12-18 months after LGS, when anesthesia is less risky and liver has reduced diameters.

Acute complications are represented by hemorrhage reported in 1-6% of cases and gastric leaks in up to 5% in the immediate period after operation [1]. Gastric stenosis has a 0 to 4 % rate of appearance for this type of operation[4]. Most cases can be solved by endoscopic dilation with balloons;however some cases need to be converted to gastric by-pass.

In an article from 2014,in a study done on 565 patients, the incidence of complications was relatively low- the authors[2] reported in 7.79% of patients infarcts of the posterior pole of the spleen, 1.42% gastric fistulas in the His angle region, with 5 deaths among these patients – 3 due to septic complications in the course of fistula, 1 due to encephalopathy and 1 as a result of myocardial infarction.

Chronic complications include strictures, malnutrition and GERD. Chronic strictures usually require further intervention. Endoscopic dilatation is an useful tool used for short segment stenosis. Successive treatments in 4 to 6weeks interval are adequate to treat stricture and ameliorate patient symptoms. In contrast, long segment stenosis and failure of endoscopic management demands a surgical intervention – laparoscopic or open seromyotomy or conversion to Roux-en-Y gastric bypass. Parikh and colleagues reported an incidence of 3.5% of symptomatic stenosis following LGS in their series of

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

230 patients; 2 patients required conversion to a Roux-en-Y gastric bypass owing to failure of endoscopic management.

In a recent study by Gehrer and colleagues[3], the prevalence of vitamin B12, vitamin D, folate, iron and zinc deficiency were reported to be 3%, 23%, 3%, 3% and 14%, respectively, after LGS In general, these investigators found micronutrient deficiencies to be less prevalent after LGS than Roux-en-Y gastric bypass; however, folate deficiency was slightly more common after LSG than Roux-en-Y gastric bypass (22% vs. 12%).

CLINICAL CASE

Our patient, a 25 years girl operated – LSG-1 year before, presented with severe malnutrition and dehydration, associating also hypokaliemia. She has been vomiting at least 4 times a day during the past 6 months and she lost almost 100 kg in 1 year (from 130 Kg, 167 cm to 37 Kg at admittance). She has done upper endoscopy 10 days ago and dilation of gastric stricture was not possible. She was told she needed surgical intervention after gaining 10 kg.

She was very pale, with brittle hair and dry skin, with Bichat's sign positive, hypotensive – 70/50 mmHg, tachycardic and refused admittance even if she was explained that she had a very high risk of death. She agreed to come and stay in hospital after solving the problems for her job. As she associated hypokaliemia we tried to correct it with 20 mEq of kalium in saline, but patient reported intense pain on peripheral i.v. infusion, so we used first 1,000mL of saline, and then Ringer and Kalium progressively.

Family reported repeated episodes of binge eating at home with ingestion of Coke and high amounts of food, after that unprovoked vomiting. Discussion with patient revealed also depression, this kind of food pattern was the patient's cry for help due to unresolved adolescence trauma, even if she had family and friends support now. We tried also to relieve the pressure from job.

Next day iv saline 500 ml, Ringer 1000 ml, Kabiven were introduced, with almost complete correction of hypokaliemia.As patient had urinary tract infection we added Gentamycin 320 mg/day and Ciprofloxacin 400 mg/day, for seven days, with good evolution.

Third day we introduced Fresubin – enteral formula – 500 ml/day, divided in 7-8 meals, no more than 100 ml/meal, associated with Osetron and Controloc on i.v. line. Patient stopped vomiting the third day and the next day we introduced small amounts of baby food – milk and egg, fruits puree, small amounts of soup with chopped meat.

By seventh day patient gained enough weight so we tried to reduce the amount of Fresubin and Kabiven and leave her on oral intake of mashed food, but this induced reappearance of vomiting. X-ray revealed no passage of barium due to complete gastric stenosis, so i.v. nutrition was resumed.

Laboratory 8 a.m. serum cortisol was more than 10 mcg/dl, so we excluded Addison disease.Patient had low TSH and low T3 levels – confirming sick euthyroid syndrome and hypotalamic amenorhhea with low Estradiol levels – 17 pg/ml.

In the last 3 days we introduced small amounts of rapid insulin – 10 U/day to improve anabolism.Patient reached 47 kg, with mild edema in the legs and was discharged in the 12th day of admittance.She still has mild hypoproteinemimia – albumin 3.2 mg/dl, total proteins 5,6 g/dl and mild hypocalcemia – 8.8 mg/dl.She was discharged with proton pump blocker and prokinetic treatment, associated with buvable ferrum sulfate.

She repeated the endoscopy and was converted to gastric by-pass after 3 days without more complications.

CLINICAL PRACTICE

Fever and abdominal tumoral masses

Augustin C. Dima[1], Teodor Artenie[1], Daniel Florea[1], Florina Bold[1], Paul I. Oprea[1]

Abstract: *49 year-old man presented to our clinic for pain in the right hypochondrium, diarrhea, and fever. The clinical examination highlights a tumoral formation in the right side of the abdomen, with firm consistency, poorly defined margins, and present mobility in the deep structures. On biological exams, leukocytosis with neutrophilia, inflammatory syndrome, and hypoalbuminaemia were identified. The first computed tomography exam described parietal thickening of the ascending colon, with infiltrative aspect, and multiple local adenopathies, lomboaortic and interaortocave. Moreover, four nodular liver tumors, with hypodense image in native examination, were identified. The lab tests for infectious diseases were all inconclusives: three hemocultures, three stool samples, and three coproparasitological exams were all negatives.*

Interdisciplinary examinations, internal medicine and infectious diseases, sustained the diagnosis of colonic neoplasm with peritumoral abscess and liver pseudo-tumoral masses. The colonoscopy did not revealed any bowel lesions relevant for neoplasia. This result as well as the bio-clinical context imposed abstention from surgical intervention.

Wide spectrum antibiotics and symptomatic treatment were initiated. But, ten days after hospitalization, the second computed tomography exam showed reduction of the ascending colon wall thickness associated with significant increases of the liver tumors is so revealed. The investigations for other possible etiologies were so continued.

Keywords: *colon tumor, intestinal amoebiasis, liver abscesses.*

INTRODUCTION

In current clinical approach of abdominal pathology one must not forgot the rare disorders whose clinical picture and imaging could mime neoplasia, pathology so frequent today.

The current diagnosis of colon tumors is made especially using imaging diagnostic methods, whose accuracy is high, facilitating anaccurate stage diagnosis, very important in determining therapeutic tactics. But it must not be forgotten also the importance of classical clinical features that could bring essential elements for the certainty diagnosis.

CASE REPORT

We present the case of a 50-years old patient, smoker, diabetic, hypertensive, who presented for right upper hypochondrium pain, diarrhea, nausea, febrile syndrome, with the onset of symptoms about 48 hours prior to presentation.

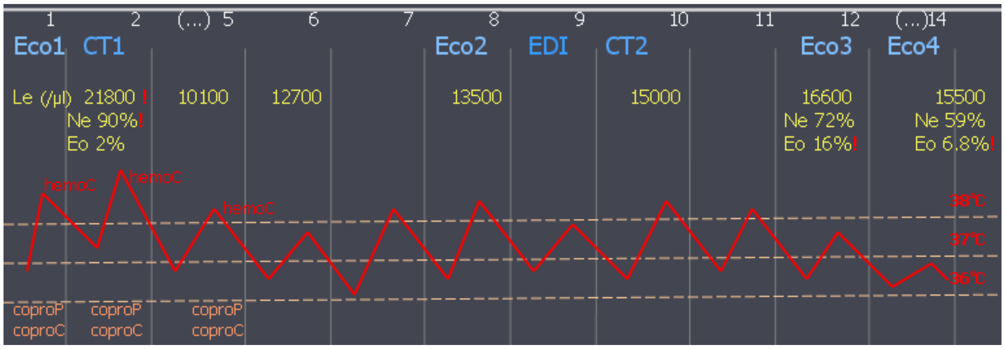
Clinical examination revealed hypochondrium and right flank sensitive abdomen, tumor mass in the right flank, with firm consistency, imprecisely defined, relatively mobile on the deep plans, without signs of peritoneal irritation, fever (38.7˚C), shivering.

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

Biologically, neutrophilic leukocytosis, inflammatory syndrome, and hypoalbuminemia were noted. Plain chest and abdominal radiography were without pathological changes (Figure 1). Abdominal ultrasound identified hypoechogenic liver formations.

Figure 1: Biological evolution during diagnostic and after specific treatment



CT exam identifies hepatomegaly and four nodular liver formations: hypodense on native examination, irregularly shaped, with uneven structure, apparently separated from their dense walls (Figures2a, 3a, 4a). In addition, a parietal tumoral formation belonging to ascending colon, located toward liver angle, showing asymmetrical narrowing partially iodophile (with a maximum thickness of 2.1cm), infiltrating the cecum – ascendant digestive wall and the adjacent fatty abdominal tissue that adheres to the liver capsule. Perilesional, lumbar aortic and interaortocaval adenopathies, (with maximum dimensions of 1.3cm) (Figures5a, 6a, 7a) were also described.

Figure 2(a, b): Computer tomography exam: first two liver masses evolution under treatment

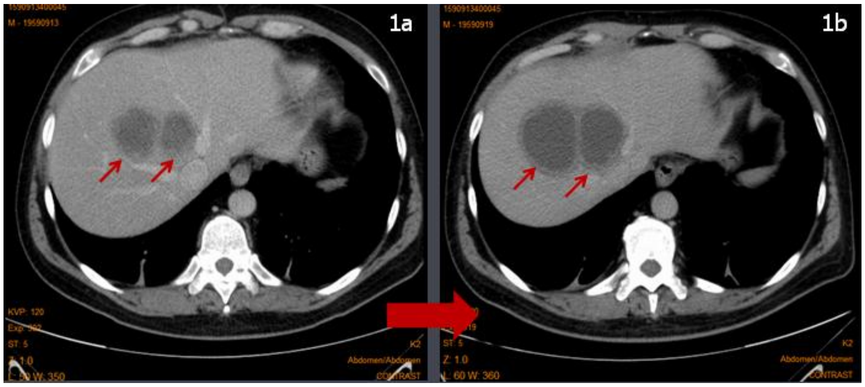


Figure 3(a, b): Computer tomography exam: liver masses evolution under treatment

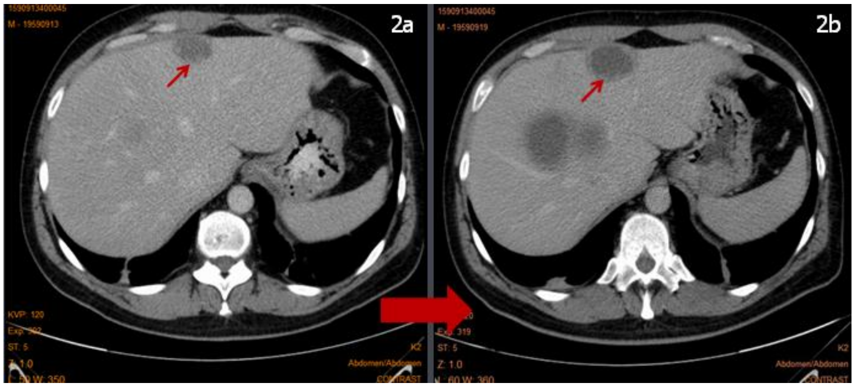

Figure 4(a, b): Computer tomography exam: liver masses evolution under treatment of the third tumoral mass

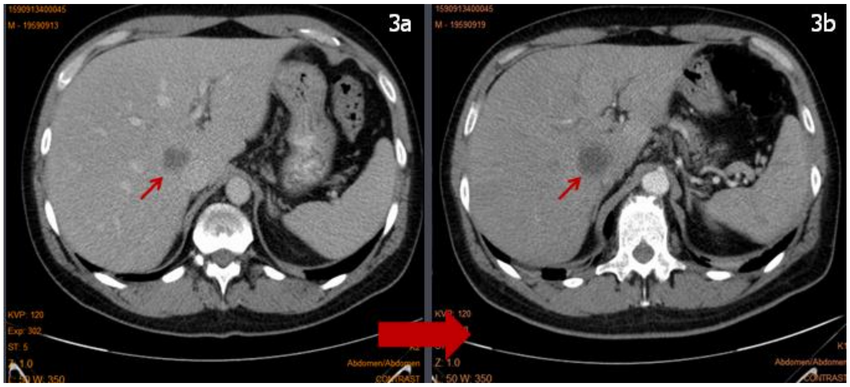

Figure 5(a, b): Computer tomography exam: colon tumor evolution under treatment

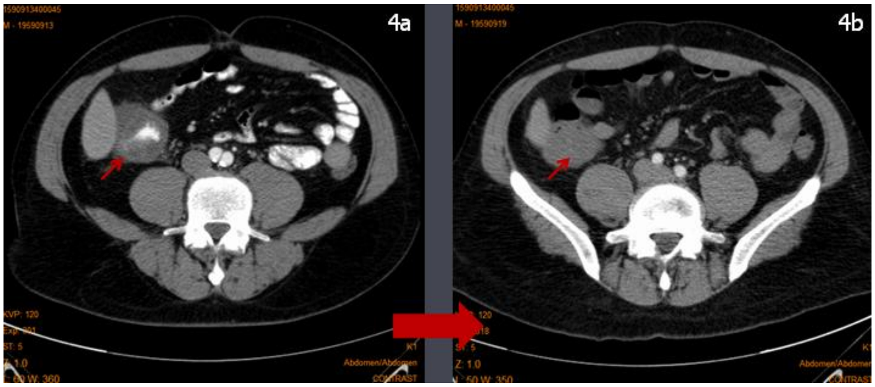

Figure 6(a, b): Computer tomography exam: colon tumor and local adenopathies evolution under treatment

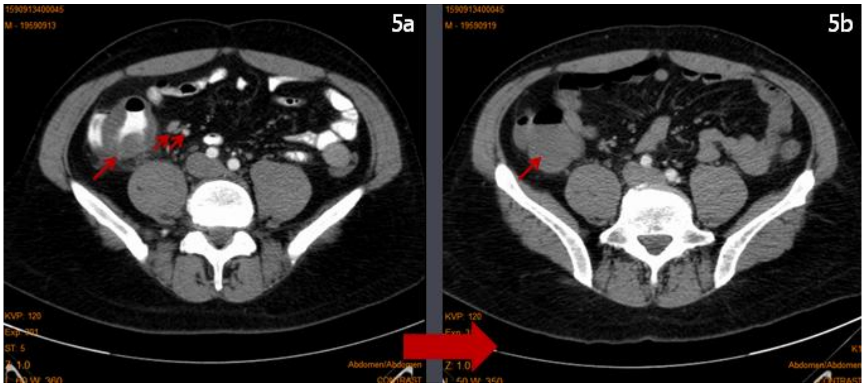

Figure 7(a, b): Computer tomography exam: colon tumor evolution

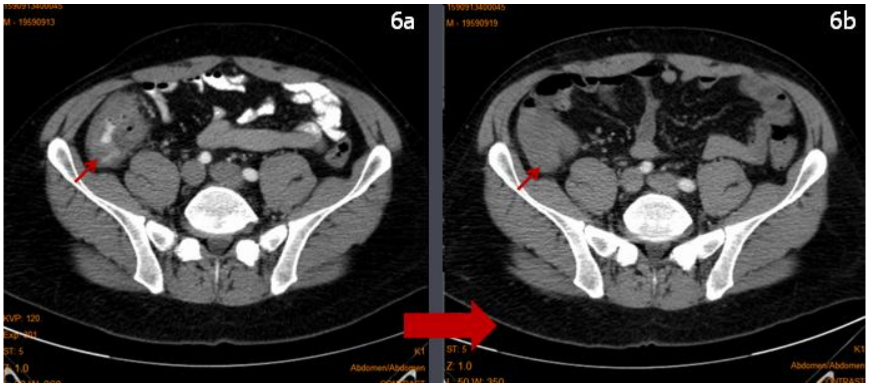

The paraclinical picture was completed with three negative blood cultures, three negative copro-parasitological exams, three negative coprocultures and tumor markers (carcinoembryonic antigen, CA 19-9, alpha-fetal protein) negative (Figure 1).

Internal medicine and infectious diseases examinations declines the eventuality of infectious or parasitic primary etiology of colony formation and supports the diagnosis of colon cancer with peritumoral abscess and septic liver determinations.

At this point, the imaging seems to support thediagnosis of ascending colon tumoral mass associated with secondary liver metastases or with local associated infection and liver abscesses.

Clinical arguments, however, given the relatively sudden symptoms onset, are pleading for diverticulitis or segmental colitis of the ascending colon with septic determinations in liver. Therefore, we consider it appropriate to postpone surgery and to make further investigations.

It was initiated treatment with broad antibiotic spectrum (imipenem – cilastatin 500 mg/ 500 mg, 4 times daily, linezolid 600 mg 2 times daily, both for 10 days and Moxifloxacin 400 mg daily for 5 days) associated with symptomatic treatment.

Lower digestive endoscopy describes in the rectum, at 4-5 cm from the anus, a 1 mm polyp covered by normal mucosa, at 10 cm from the anus a 2 mm sessile polyp, covered with congestive mucosal, biopsy was performed. In the sigmoid colon, to about 25 cm, a 10 mm semi pedunculated polyp, cylindrical, covered by the congestive mucosa, supple for biopsy. At the descending colon polyp plan, ovoid of 7-8 mm, covered with inflamed mucosa, supple for biopsy. Transverse and ascending colon without changes.

Caecum, opening of appendix and the ileocecal valve without modifications.

The morphopathologic diagnosis of colon polyps was of tubular adenoma. So, the endoscopic examination does not argue for tumor etiology.

The evolution under treatment was favorable: reducing the number of daily diarrheal stool (from 10 to 12 per day to 2-3 per day) and also fever – under vesperal fever and the overall condition has improved. Biologically, continuing with leukocytosis with neutrophilic, but at lower values and the increasing of cholestasis defining liver enzymes (Figure 1).

We repeat, on day 10 – from the admission – the CT examination and we see a significant increase in volume of liver formations, the largest with a diameter of about 7cm, with better separation than previously, clear evidence of the relatively thick walls and of clear fluid content (Figures2b, 3b, 4b). Also, the marked reduction in the ascending colon thickness and reduction in the size of abdominal adenopathy (Figures5b, 6b, 7b) were noted.

Diagnosis of infectious disease is gaining before a possible neoplastic etiology, se we ask forparasitology and infectious diseases check-up and serological determinations.

Positive diagnosis is supported by the presence of Ig G type anti-Entamoeba histolytica antibody (negative Entamoeba histolytica antigen, negative Echinococcus antibodies, negative Giardia duodenalis CoproAg and Cryprosporidium CoproAg) for which specific treatment is initiated.

Thus, the positive diagnosis was: liver amoeba disseminated abscesses in both lobes, in remission and intestinal amoebiasis affecting the ascending colon, submitted.

The patient’s evolution after the initiation of the etiological treatment was favorable with improvement of the general condition, normalization of blood counts at two weeks of antiparasitic ambulatory treatment and marked reduction of liverabscesses dimension with their disappearance in a year.

DISCUSSIONS

Entamoeba histolytica is a protozoan that is an important health problem in tropical and subtropical countries [1]. Infection is fecal-oral, 90% of those affected remain asymptomatic, being determined by ingestion of food contaminated with parasite cysts [2]. It affects particularly the gastrointestinal tract (more frequently the check and ascending colon) and liver [3].

The difficulty of diagnosis in this case was given by the initial CT imaging appearance of ascending colon tumor, accompanied by the negative coprocultures and coproparasitological exams.

Imaging appearance of colonic amoebiasis mimicking neoplastic pathology has been described in the literature, but this presentation as a colon tumor formation remains a rare occurrence[4][5]. Most frequently, the colonic amebiasis diagnosis is done by highlighting the parasite in the stool, the examination of three successive stools leading to a positive diagnosis in 70% of patients [6].

The correct diagnosis in the presented case was obtained only after achieving immunological determinations, serology for Entamoeba histolytica is positive in up to 90% of patients with amoebic colitis [7].

Also, another feature that hindered the diagnosis was the initial presence of neutrophilic leukocytosis, with no eosinophilia (Figure 1), which could be explained by possible plurimicrobial superinfection of the parasite gateway from ascending colon.

After starting antiparasitic treatment an increase in eosinophils in serum is observed, most likely secondary to parasitic destruction and thus the emergence of new antigenic elements.

Important in the proper management of this patient was refraining from any surgery and introduction of specific therapy (Metronidazol) despite the pressure brought by imaging and biological data. Surgery in Entamoeba histolytica infection is a must in cases of acute colitis with necrosis and perforation when it may be necessary even total colectomy [8][9] and could also be followed by many complications.

Another problem of therapeutic tactic was the discussion on the need for drainage of liver abscesses, their sizes being significant. The ultrasound tracking has shown that the effective antiparasitic treatment was enough, observing the gradual decrease of their sizes, with their disappearance one year after the initiation of antiparasitic treatment.

In general, the literature does not support the need of drainage for uncomplicated liver amoebian abscesses [10]. Could be drained big liver abscesses (>300 cm^3) or when there are questions about the etiology of liver abscess, like in the case of pyogenic liver abscess [11][12] when cultures from drainage samples could be informative on the etiology and further treatment.

There is no secret to anyone that we live in a society marked by uncertainty and unpredictability, a society in which information flows through all communication channels, both in cyberspace and in mass media. Therefore, it is increasingly difficult for the „modern man” to decide upon the veracity and value of the informational content so that, eventually, based on the latter, he can upgrade his knowledge in any area of interest.

In such a context, it is difficult for society to control its evolution and to identify valuable markers that would ensure a valid growth in time and space. Lacking history, hierarchy, elite, rules and order, one can talk neither about the development of an organization nor about the development of society as a whole.

I think we have all passed, in recent years, through a "period of resistance" to the wave of non-values that invaded us and created an organic need to protect and preserve the values our parents and grandparents taught us. Despite the appearance of resignation, the accumulation of such energy has made us stronger, more aware of our role and this made us persistent and gave us the power and the chance to change our future and our children’s future.

Returning to the reason that brought us together, by means of this page, you – the reader and me – the author, I can say without any doubt that every cell of my being has reacted with emotion at the course and unrest of the last years of military medicine. It was only when I became the Commander (General Manager) of the "Dr. Carol Davila" Central Clinical Emergency Military Hospital (SUUMC), that I fully understood the huge potential of this noble profession – military doctor – potential generated by the excitement of the trust and respect offered each day by the public opinion in general and especially by citizens.

I have always considered that medicine is a field in which evolution ignores borders, bureaucratic rules, customs and paradigms, because trying to rescue somenone’s life is such a pure and noble approach that no sacrifice for this purpose can ever be considered too big.

This year the "Dr. Carol Davila" Central Clinical Emergency Military Hospital, a symbol for the history of Romanian society, celebrates the honorable age of 185 years of tradition, trust and professionalism, dedicated to research, development and innovation in medicine. 185 years in the service of life, without any deviation from the fulfillment of the two oaths: the military oath and Hipocrate's oath.

We should always keep, in our minds and hearts, the memory of those who, on the battlefield of the two World Wars, nursed their fellows and some of them even lost their lives trying to rescue the latter, the persistence of the struggle with their own limits taking care of the victims of the earthquake that shook Bucharest in March 1977; the emotion lived when faced with the young soldiers, victims of the construction of Transfăgărăşan and of the Danube – Black Sea Canal. Recently, the victims of the tragic fire at Club Colectiv were a challenge for the doctors and nurses in our hospital. All the departments of the hospital worked as a real efficient and dedicated team having only one purpose: to save the lives of the victims who were our patients.

During 185 years, together with the Romanian Army, we have been in the service of the country and of the population, doing our best in our duty with modesty, professionalism, ethics and team spirit. We did not pose as mentors, although here, in this area of health, the foundations of medicine, pharmacy and education in this field in Romania were laid. Medical and surgical specialties were also born here, specialties that today are spoken of as a fact, not as a gift from our ancestors, military doctors – thoracic surgery, urology, epidemiology etc.

The only thing military medicine was deprived of until now, is "a single voice of professionals" in this field, segment considered by most of our civil colleagues relatively narrow as area of specialty and therefore lacking the capital injection necessary to ensure its technical and cutting-edge technology, which apparently decreased our competitiveness in the market of medical services provided. Not true! In the absence of facilities, the human resource of this system accepted the professional challenge and approached a sphere of increasingly complex pathology, and on the other hand, the interdisciplinary collaboration has strengthened human links and increased our performance as professionals. It is true that until three years ago, we may not have had the latest surgical technologies but we beat cancer through the physician's sharp spirit, the surgeon's, the pathologist's and oncologist's experience.

Three years do not mean anything for a hospital, but for someone diagnosed with a relentless disease they mean everything... This was one of my thoughts that motivated me to develop centers of excellence – assigned and equipped to the highest standards – capable of providing prevention, treatment and monitoring of disease in the oncologic pathology, strokes, cardiovascular diseases and digestive diseases; lung transplant – a medical and surgical activity of high human and professional performance, which also involves a great responsibility assumed by SUUMC, on medium and long term, for patient's life quality, service which is not available at this time, in any other public hospital in Romania; neurological and neuromotor rehabilitation center for the veterans from the operation theaters.

Romania's geopolitical and geostrategic situation, as a state located at the EU and NATO border, obliges me, at the same time, to analyze the development of the operational medicine component in the Central Military Clinical Emergency Hospital "Dr. Carol Davila", so that, in wartime, we can be prepared to face the specific challenges related to the pathology and casuistry of a military confrontation.

Both as a doctor, and especially as the manager of the Central Military University Emergency Hospital "Dr. Carol Davila", I understand that the expectations of the whole society towards military medicine are very high, whether we speak of peace or war. People expect us to be a performant regional hospital, which provides at safe and high standards, a medical act comparable to that granted by a specialty hospital from abroad, while in wartime the hospital should become an elite military medical facility, ROL 4, able to provide medical care to the standards required by our NATO allies.

With a background of 185 years, the Central Military Clinical Emergency Hospital "Dr. Carol Davila", returns in force, as an important player on the market of medical services in Romania and elsewhere, proving that to the three qualities that have pierced the veil of history – TRADITION, TRUST, PROFESSIONALISM –

we should add the key to success in order to ensure the evolution of this type of institution, within the criteria imposed by the information society, consisting of flexibility, predictability, resilience and responsiveness in the case of a crisis or disaster.

As arguments in support of the above, I would point out some key milestones of the work of the last three years, namely, that SUUMC is the only institution in the medical network of the Ministry of Defence running projects from European funds for research, development and innovation in the medical field. It is connected to military medical centers in the Balkans, by means of the collaboration platform of telemedicine type, IMIHO. The hospital has developed collaboration agreements with major centers in the field, in the country and abroad (Belgium, Austria, Turkey and Serbia) to conduct training programs for medical staff and it is a serious instruction and training institution for students and residents, as a consequence of the extension of academic and university partnerships.

At the beginning of a new stage of life, I hope that The Romanian Journal of Military Medicine, in this new format, supported by a high scientific editorial board, will fulfill its objective to disseminate knowledge, to bring added value to the market of specialized publications in this field, from Romania and from abroad, to support the research activity and to motivate young people who make their first steps on the road to a career dedicated to the most precious thing that we all receive: health.

As a team player who strongly believes in the power of military medicine elite, in the interdisciplinary dialogue of this discipline, I assure you that I will support this approach, as I have already done it so far, in order to increase its quality every year and to borrow from the brilliance of the historic celebration of 185 years from the signing of the birth certificate of the Army Hospital.

Management of Helicobacter pylori infection – new insights

Andrei Gavrilă[1],Andrada Popescu[1], Petruț Nuță[1], Raluca S. Costache[1,2], Mariana Jinga[1,2], Săndica Bucurică[1,2], Bogdan Macadon[1], Mihăiță Pătrășescu[1], Florentina Ioniță Radu[1,3]

Abstract: *Introduction: Our objective is to review current international guidelines for Helicobacter Pylori treatment and our department`s experience in this field.*

Materials and methods: Helicobacter pylori is a Gram-negative, microaerophilic bacterium that can be found mainly in the gastric mucus or on the inner surface of the gastric epithelium, infecting up to 50% of the population. Colonization with this bacterium is not a disease in itself, but can cause chronic gastritis, peptic ulcer, gastric cancer and MALToma. Because of this, infection with H. pylori continues to be a major healthcare burden, especially in less-developed countries.

A multitude of non-invasive tests are available for the diagnosis of Helicobacter pylori infection (blood antibody, stool antigen or urea breath test), but the most reliable method of diagnosis is histological examination from two sites after endoscopic biopsy, combined with either a microbial culture or rapid urease test.

Treatment of Helicobacter pylori infection is becoming a challenge, as eradication following standard triple therapy is decreasing worldwide due to increased bacterial resistance against antibiotics, which has led to the development of newer therapies such as the sequential treatment in which a PPI and amoxicillin is given for 5 days followed by a PPI, clarithromycin and metronidazole for another 5 days, or the quadruple therapy based on a PPI, bismuth subcitrate, metronidazole and tetracycline for 10 days.

Results and conclusion: H. pylori infection remains one of the most challenging infectious diseases, causing high morbidity and mortality, mainly because none of the actual antibiotic therapies can provide successful eradication.

Keywords: Helicobacter pylori, ulcer, adenocarcinoma, antibiotics, PPI

INTRODUCTION

Helicobacter pylori (Hp) is a helix shaped, Gram-negative, microaerophilic bacterium that can be found mainly in the gastric mucus or on the inner surface of the gastric epithelium[1]. Hp infection is the most common chronic infection in humans, but colonization with this bacterium is not a disease in itself. Although most infected individuals remain asymptomatic for life, Hp is responsible for a number of pathological manifestations including chronic gastritis, gastric or duodenal ulcer, adenocarcinoma

[3] TituMaiorescuUniversity, Bucharest

of the stomach or gastric mucosa–associated lymphoid tissue (MALT) lymphoma[2].

THE DISCOVERY OF HELICOBACTER PYLORI

The Helicobacter pylori bacterium was discovered by two Australian researchers by the name of Barry Marshall and Robin Warren, who also deciphered its role in gastritis and peptic ulcer disease (PUD)[3]. Their discovery was published in 1982, at a time when it was a long-standing belief that stress and lifestyle factors were the major causes of PUD. The scientific community of the time met their findings with skepticism and a lot of criticism, refusing to belief that any life-form can survive in the acid medium of the stomach. This is why it took a very long time and effort for their discovery to become widely accepted[4].

Marshall`s 1985 “self-help” experiment rebutted the “stress and life-factors” dogma. He first underwent gastric biopsy to show the absence of the bacterium, then, to the horror of his assistant, ingested a turbid, foul-tasting solution of Hp. Soon he developed a number of symptoms including nausea and vomiting and an endoscopy with biopsy was performed, which revealed signs of gastritis and the presence of Helicobacter Pylori[3].

EPIDEMIOLOGY

Transmission of Hp is believed to be by gastro-oral or fecal-oral routes as the bacterium can be cultured from vomitus or diarrhea stools. Therefore, the overall prevalence of infection can be influenced by lack of proper sanitation and basic hygiene, of safe drinking water, as well as overcrowding, making it a public-health issue in developing countries[1].

One of the most important risk factors is childhood socioeconomic status, meaning that infection is acquired at an early age, especially in developing countries. It is common for spontaneous clearance to occur during early childhood, but the chance of reinfection is greater in developing countries compared to developed ones – where it is estimated to occur in less than 0.5% of cases per year[5].

Due to these factors, prevalence of infection can reach up to 80 % by the age of 20-30 in developing areas, whereas in developed countries prevalence is less than 20 % in individuals younger than 30 years, but can reach up to 40-50 % in those 60 of age or older[2].

PATHOPHYSIOLOGY

Clinical outcome of Hp infection is dependent on sophisticated interactions between the bacterial, host and environmental factors. In order to promote chronic infection, H. pylori first has to survive in the harsh acidic environment of the gastric medium[6]. One of the most important bacterium survival technique is the “acid acclimation mechanism” that adjusts periplasmic pH by regulating activity of urease. Another factor on which successful colonizationof the gastric epithelium depends is bacterial motility provided by the presence of 4 to 6 functional unipolar flagella. Recent studies show that peptidoglycan-degrading enzymes are necesary for the proper assembly ofthese flagella[7]. After colonization, adherence to gastric epithelial cells is necessary and this is done thanks to a variety of outer membrane proteins (OMPs), several of which can serve as adhesins, the most important being BabA and SabA. H. pylori employs genetic diversification to adapt to the host immune response and promote persistent infection[8].

This pathogen possesses various virulence factors known to be significant in the induction of disease during infection. One of the most studied effector molecule is cytotoxin-associated gene A (CagA) which is injected into the host cell upon contact via the cag pathogenicity island (cagPAI)-encoded typeIV secretion system. Once intracellular, CagA localizes on the inner surface of the celular membrane and is subjected to a tyrosine-phosphorylation process by Src family kinases. The phosphorylated CagA subsequently induces a signaling cascade, causing proinflammatory responses in epithelial cells[9]. While the literature is contradictory, some studies, including those of Kang et al. and Papadakos et al., sugest that inflamation is induced via the nuclear factor (NF)-kB signaling pathway and subsequent interleukin (IL)-8 secretion[7]. Taking this into consideration, and also the fact that CagA translocation and phosphorylation are mediated by cholesterol-rich microdomains of the plasma membrane, Lin et al. found that methylantcinate B, a triterpenoid extracted from the Antrodia camphorata mushroom, attenuates CagA translocation and phosphorylation and inhibits CagA functions, including NF-kB pathway activation and IL-8 secretion; but further in vitro research is needed to assess the possibility of a new, antibiotic-free regimen[9].

DIAGNOSIS

The diagnostic procedure of Hp infection can be difficult due to the fact that up to 80-85% of infected individuals are asymptomatic, while the rest develop a series of non-specific symptoms, such as nausea, vomiting, abdominal pain, heartburn, halitosis or diarrhea[1]. This is why specific indications for testing were stipulated. These include active or documented history of peptic-ulcer disease, early-stage gastric MALToma, early gastric cancer, or uninvestigated dyspepsia in high prevalence areas[4]. Testing for the primary prevention of gastric cancer can be performed in individuals with high risk, such as those with family history of gastric cancer, or first-generation immigrants from a region with high-incidence for this malignancy. Some physicians recommend testing prior to starting long-term non steroidal anti-inflammatory drugs or proton pump inhibitors (PPI)[10].

There is also clear evidence that Hp can be involved in the pathogenesis of some extra digestive diseases, with a clear indication to test for infection in individuals with unexplained iron-deficiency anaemia, idiopathic thrombocytopenic purpura (ITP) and vitamin B12 deficiency[11]. Other studies have tried to find a link between Hp infection and some cardiovascular, lung, hepatobiliary or neurological disorders, but failed to produce an unequivocal causative association thus far[12].

Several methods are currently available for detecting Hp infection. Unfortunately, there is no gold-standard diagnostic test due to the fact that every method has it`s limitations and disadvantages [13] (as seen in table 1).

Table 1: Diagnostic tests for Helicobacter pylori infection [14]

Endoscopic Testing	**Advantages**	**Disadvantages**
A) Histology	Excellent sensitivity and specificity	Expensive. Requires infrastructure and trained personnel
B) Rapid urease testing	Inexpensive. Provides rapid results. Excellent specificity and very good sensitivity.	Posttreatment sensitivity significantly reduced
C) Culture	Excellent specificity. Allows antibiotic sensitivities determination	Expensive. Difficult to perform. Not widely available.
D) Polymerase chain reaction (PCR)	Excellent sensitivity and specificity. Allows antibiotic sensitivities determination	Not standardized across laboratories. Not widely available
Nonendoscopic Testing	**Advantages**	**Disadvantages**
A) Antibody testing (quantitative and/or qualitative)	Inexpensive. Widely available Very good NPV	PPV dependent upon background Hp prevalence. Not recommended after Hp therapy
B) Urea breath tests (^{13}C and/or ^{14}C)	Identifies active Hp infection. Excellent PPV and NPV regardless of Hp prevalence. Useful before and after Hp therapy	Reimbursement and availability remain inconsistent
C) Fecal antigen test	Identifies active Hp infection. Excellent NPV and PPV, regardless of Hp prevalence. Useful before and after Hp therapy	Polyclonal test less well validated compared to the UBT in posttreatment settings. Monoclonal test appears reliable before and after Hp therapy.
The sensitivity of all tests (endoscopic and nonendoscopic) that identify active Hpi infection is reduced by the recent use of PPIs, bismuth, or antibiotics PPI = proton pump inhibitor; NPV = negative predictive value; PPV = positive predictive value; UBT = urea breath test.		

Table 2: Possible reasons for Helicobacter pylori treatment failure.

1	resistance acquired by mutations
2	the low gastric pH limits antibiotic efficacy
3	antibiotic concentration can be insufficient if there is a high bacterial load
4	existence of sanctuaries to which antibiotics do not diffuse
5	existence of viable bacteria in dormant forms not accessible to antibiotics
6	impaired host mucosal immunity
7	risk of re-infection
8	lack of patient compliance (due to adverse effects or poor understanding of complex antibiotic regimen)

TREATMENT

Historically, various combinations of antibiotics have been used to eradicate the infection, however, no optimal treatment has yet been defined, as there is not a single drug regimen that can eradicate it. There are many factors that have increasingly compromised the effectiveness of most commonly used therapies (as seen in table 2)[1].

These factors have reduced the eradication rates to unacceptable levels (< 80% in some geographic areas). As a response, new treatment strategies have been studied and recently been validated to replace the standard ones[15].

Eradication therapies should be guided ideally by individual susceptibility testing. As this is not cost-effective, local antibiotic resistance patterns should dictate the regimen. Another factor that influences the treatment strategy is drug availability in different countries[16]. These regimens can be divided into first-line treatment and second-line or rescue treatment and are summarized in table 3[1].

Table 3: Treatment regimens for Helicobacter pylori infection

First-line therapies		
Regimen name	*General characteristics*	*Duration*
"Standard triple treatment"	simultaneous PPI + clarithromycin + amoxicillin (each twice daily)	7 days
10 or 14 days triple	simultaneous PPI + clarithromycin + amoxicillin (each twice daily)	10 or 14 days
Sequential therapy	5 or 7 days simultaneous PPI + amoxicillin, followed by 5 or 7 days simultaneous PPI + clarithromycin + 5-nitroimidazole (each twice daily)	10 or 14 days
Quadruple therapy	Simultaneous PPI (twice daily) + bismuth subsalicylate, metronidazole and tetracycline (each 4 times daily)	10 or 14 days
Second-line and rescue therapies		
Regimen name	*General characteristics*	*Duration*
Concomitant therapy	Simultaneous PPI + 3 antibiotics (often amoxicillin, clarithromycin, and 5-nitroimidazole) (each twice daily)	7, 10 or 14 days
Levofloxacin therapies	Levofloxacin will replace clarithromycin in triple, sequential or concomitant regimens	7, 10, 14 days
Hybrid therapy	7 days simultaneous PPI + amoxicillin, followed by 7 days simultaneous PPI + amoxicillin + clarithromycin + 5-nitroimidazole (each twice daily)	14 days
Rifabutin triple therapy	PPI + amoxicillin + rifabutin (each twice daily)	14 days

PPIs are mandatory compounds in every regimen and are administered twice daily at standard doses: omeprazole 20 mg, esomeprazole 40 mg, lansoprazole 30 mg or pantoprazole 40 mg (with studies showing higher eradication rates for the more potent second-generation PPIs – namely esomeprazole). Standard antibiotic dosages are used in all treatment regimens: amoxicillin 1 g, clarithromycin 500 mg, metronidazole 500 mg, tinidazole 500 mg, bismuth subsalicylate 524 mg or bismuth subcitrate 420 mg, tetracycline 500 mg, levofloxacin 500 mg, and rifabutin 300 mg[17].

A recently published meta-analysis by Li et al. has compared many of the available regimens for efficacy and tolerance. In terms of efficacy, the standard triple therapy was outranked by all other regimens, with the best eradication rates for the sequential therapy amongst first-line treatments and for the concomitant therapy amongst rescue treatments. The same study has shown that increased treatment duration improves eradication rates, but at the same time enhances the likelihood of adverse effects, lowering patient compliance – almost all rescue regimens were poorly ranked in terms of tolerance[18]. Because of the fact that none of these regimens is ideal, eradication should always be assessed, preferably using a non-invasive test (eg: urea breath test or stool antigen test). Confirmation of eradication can also provide an early image on the pattern of antibiotic resistance in a specific population[15].

All this effort in treating Hp infection is justified by the many benefits of eradication for patience with PUD, but also some malignant conditions. For example a cured individual has better ulcer remission rates for both gastric and duodenal ulcer and does not need maintenance acid suppression therapy after eradication and ulcer healing[10]. It is also more cost-effective and superior compared to maintenance acid suppressive therapy in preventing duodenal ulcer[1]. As for malignant pathologies, early stage low-grade MALT lymphoma can be cured by Hp eradication up to 80% of cases and there is also the possibility of regression or decrease in progression of precancerous gastric lesions (atrophic gastritis and intestinal metaplasia) after eradication[15].

Other studies have shown inverse associations between Hp infection and the prevalence of certain diseases. A recent study published by Rubenstein et al. confirmed prior studies that showed a strong negative association between Hp infection (particularly the cagA strain) and erosive esophagitis, Barrett's esophagus or adenocarcinoma of the esophagus. However, contrary to the prevalent hypothesis explaining this association, they were unable to detect a negative association between Hp infection and gastroesophageal reflux disease symptoms[19]. Lebwohl et al. found a strong inverse relationship between Hp presence and celiac disease (CD), but failed to establish the mechanism by which Hp might be protective against CD[20]. Other studies have postulated that Hp is protective against some extradigestive conditions, especialy asthma and other allergic pathologies in children[21].

THE ROLE OF PROBIOTICS IN HP MANAGEMENT

Probiotics are defined by the World Health Organization (WHO) as "live microorganisms which, when administered in adequate amounts, confer a health benefit on the host". Most commonly used in clinical practice are lactic-acid-producing micro-organisms (Lactobacillus spp. or Bifidobacterium spp.). Lactic acid produced by these probiotics can have a direct antimicrobial effect by lowering the pH, but can also inhibit the Hp urease. There is also increasing evidence in animal models that some strains of probiotics can inhibit H. pylori growth by competing with different adhesion sites in the gastric mucosae. Another mechanism being stipulated is that some probiotics can increase the expression of the MUC2 and MUC3 genes, which can subsequently lead to an increase of mucus thickness in both antrum and corpus after long-term probiotic intake.

Many studies have been conducted in this field and by analyzing some of them Enzo et al. have reached the conclusion that the use of probiotics as an adjuvant to PPI–antibiotic treatment could improve eradication rates, but the main benefit of this association is the prevention of side-effects, leading to better patient compliance[22].

FUTURE THERAPIES

Efforts to develop a vaccine against H. pylori began in early 1990`s with initial attempts to promote a localized mucosal immune response in the stomach via oral vaccines. Recently, an intramuscularly trivalent vaccine (recombinant Cag-A, Vac-A, and neutrophil-activating protein) was developed, but failed to induce immunity, despite the fact that these antigens were recognized by the host's humoral and cellular immune systems. Although considerable progress has been made in understanding the innate and adaptive immune response against Hp infection, it is still uncertain how to promote the development of host immunity with the final goal of creating a successful vaccine[23].

DISCUSSIONS AND CONCLUSIONS

Despite the constant progress made in the management of Helicobacter pylori infection, it is still considered a major public health issue due to it`s high prevalence (especially in developing countries) and various conditions that can arise from it (even though 80-85% of infected individuals are asymptomatic). The main reasons for treatment failure is resistance acquired by mutations and lack of patient compliance and recent studies are showing that the standard triple therapy is out-performed in effectiveness by most other treatments. Probiotic adjuvant therapy appears to have a clear effect in reducing side effects, but insufficient data exists to conclude that their use improves eradication rates. Knowing that there is no "gold-standard" in Hp eradication therapy and falling short of the individual susceptibility testing goal, the regimen should be dictated by local antibiotic resistance patterns.

The use of low-intensity ultrasound system in Orthopedics for treatment of fractures

Alexandra Șopu[1]

INTRODUCTION

The treatment of non-union or delayed union of fractures includes a growing number of approaches and techniques, one of which is bone growth stimulation using low-intensity ultrasound (LIUS). The treatment is effective, painless and safe. Currently, Exogen is the only device marketed worldwide that uses LIUS to influence the fracture healing process.

THE HEALING PROCESS OF THE FRACTURED BONES

All the fractured bones have to go through a healing process. This is true in cases of surgery or injury. The process of bone healing has three stages. The first stage is inflammation. This starts when the bone has been fractured. Bleeding always takes place in the area of the fracture. This leads to clotting of blood and inflammation in the area. This provides the framework of a new bone. The second stage is bone production. With time, the clotted blood formed in the inflammation stage is replaced by cartilage and fibrous tissues. As the healing continues, the hard callus replaces the soft callus. This can be seen by x-rays some days after the fracture [1, p 20]. The last stage is bone remodeling. This stage goes on for months. In this stage, the bone continues to become compact and returns to its original shape and structure. The blood circulation in the area of the fracture improves. Once some bone healing has taken place, weight bearing encourages the bone remodeling stage [2, p 99].

THE EXOGEN ULTRASOUND BONE HEALING SYSTEM

This is an approved and clinically tested system for treatment of bone fractures. Exogen makes use of the painless ultrasound waves in order to activate the cells that are near the site of the fracture. This speeds up the natural repair process [3, p 1999].

Clinical studies have shown that the system accelerates the healing process of the fractured bones by 38 % in acute fractures [4, p 655] and 86% in non-union or delayed union. It has been shown that Exogen can improve the fracture healing process of older people, those who take tobacco and those who are obese, cases in which the healing process might be delayed. Exogen system can accelerate the process of healing as much as 50 % for the patients who smoke [6, p 254].

The picture below offers a basic explanation of how Exogen works at the cellular level.

To enhance bone healing, Exogen releases low intensity pulsed ultrasound waves at the point of the fractured bone. This jump-starts the natural healing process of the body. The waves move through the skin and the soft tissues to stimulate the critical cells

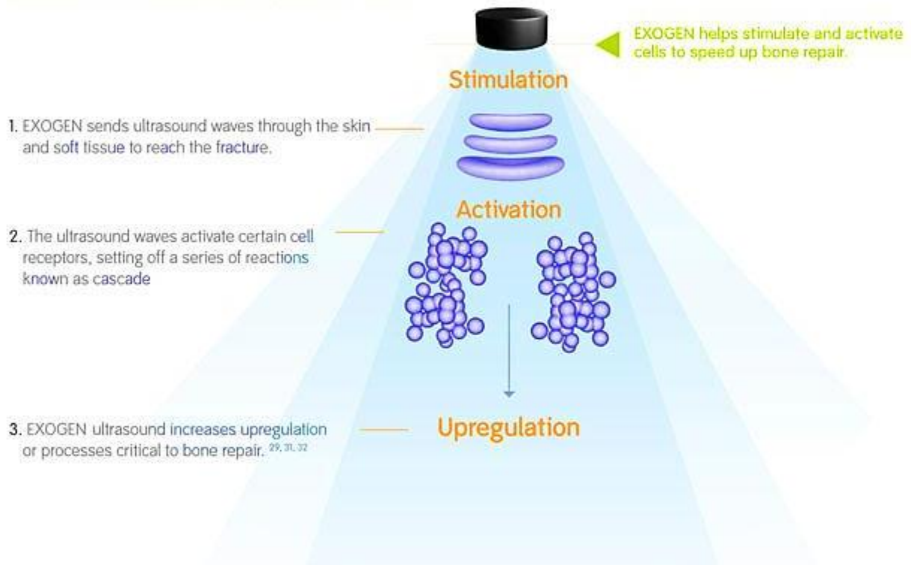
involved in bone healing.

Figure 1: The way Exogen Accelerates the Healing Process of a Fractured Bone [14]



EXOGEN helps stimulate and activate cells to speed up bone repair.
Stimulation
1. EXOGEN sends ultrasound waves through the skin and soft tissue to reach the fracture.
Activation
2. The ultrasound waves activate certain cell receptors, setting off a series of reactions known as cascade
Upregulation
3. EXOGEN ultrasound increases upregulation or processes critical to bone repair. 29, 31, 32

In order to understand the role that the ultrasound plays in healing of the fractured bones, there is a need to understand what it is and how it works. It uses transcutaneous acoustic energy. The piezoelectric crystal produces sound waves which are transmitted through the various body tissues to make a number of changes which are implicated in the tissue healing [8, p 1098]. The density of the tissue is directly proportional to the sound waves that the tissue absorbs. The bone possess high density which makes the ultrasound waves to target the areas which may be affected or have bony abnormalities.

Low intensity pulse ultrasound (LIPUS) specifically works as a potential noninvasive therapeutic in healing of fractures. The waves which are produced by LIPUS introduce micromechanical stress in the area that has been fractured. This stimulates the cellular and molecular responses that are involved in the normal fracture healing. The osteogenic and angiogenic effects caused by the administration of LIPUS are non-thermal. The effects are mechanical in nature with a temperature variation of less than 10C [9, p 802].

The optimum parameters used to archive the maximum benefits of LIPUS are: a pulse width of 200us, an intensity of 30 Mw/cm2 and a 1.5 MHz frequency repeated at 1 kHz every day for 20 minutes [6, p 254].

HOW ULTRASOUND EXERTS MECHANICAL STRESS

There are two mechanisms by which LIPUS induces the mechanical stress in tissues. First it achieves it by displacement of the ends that are fractured and secondly by cavitation.

Research shows that displacement of the fractured ends occurs in at Nano metric scale [9, p 802]. This then stimulates the cellular and the molecular pathways which are involved in the bone healing process [10, p 1022]. It has been shown that LIPUS causes micro motion at the hard and soft tissues interface also. This action produces a mechanical stimulus that is more salient to the integrin mechanoreceptors which take part in osteogenic differentiation and cellular signaling. However it is not yet clear through the available research which displacement mechanism is dominant [11, p 703].

The second mechanism involves the acoustic streaming and cavitation. This mechanism promotes the idea that the sound waves that are emitted from LIPUS allow the accumulation of gas bubbles in the tissues and the cells [12, p 411]. This creates a cavity which gives room for the acoustic streaming. The streaming leads to turbulence or circular flow in the fluids from the tissues as the sound waves move around the bubble of gases. The acoustic streaming produced increased cell permeability. Once this has happened, the blood pressure rises in the area where the fracture has occurred. The increase in the blood pressure leads to the acceleration of healing by ensuring that there is sufficient gas exchange and the delivery of nutrients to the site. When the cavitation is not stable, the bubbles burst and the resultant energy stimulates the surrounding tissues [13, p 2642].

THE EFFECT OF LIPUS ON CELLS AND MOLECULES

There have been studies that have demonstrated the ability of LIPUS to promote fracture healing through the alteration of molecular and cellular mechanisms which are involved in the process of healing. Integrins are crucial in signaling modulation involved in fracture healing [14, p 345].

They act as mechanoreceptors and are also reactive to pressure changes and vibration caused by LIPUS in the cells environment. The mechanical stimuli increase the clusters of integrin on the fibroblasts. They also up regulate the mRNA expression of the integrin in osteoblasts [15, p 284]. The changes that occur enhance the sensitivity of the respective cells to motion and increase the cells intercellular signaling capacity. An important outcome associated with the intercellular signaling induced in the osteoblasts is the increased activation of ocyclooxygenase-2 enzyme.

This increases the production of prostaglandin which is critical in the mineralization during the process of endochondral ossification especially on the soft callus [16, p 660]. The endochondral ossification which is enhanced by LIPUS leads to formation of the bony callus by the process of augmented mineral deposition [17, p 77].

LIPUS also stimulates the differentiation of the cells which are involved in the process of fracture healing, chondroblasts, fibroblasts, mesenchymal and osteoblasts. Additionally, it increases the way aggrecan expresses itself [18, p 1957]. Aggrecan is a stimulator of chondrogenesis. Presence of aggrecan accelerates the differentiation of chondroblasts into chondrocytes. The production of chondroitin sulfate at the site of injury is accelerated by the presence of more chondrocytes.

Chondroitin sulfates are essential components in supporting bonny and cartilaginous structures. Because of the cavitation process aforementioned, LIPUS increases pressure at the site of injury due to the increase in the vascular permeability [19, p 727]. The increase in pressure has been associated with mesenchymal stem cells differentiation which enhances the development of fibro cartilaginous callous.

LIPUS increases the expression of the early osteogenic genes which include osteonectin, the insulin growth factor and osteopontin. These genes have an important role in making sure that proper osteoblast differentiation takes place [20, p 3190]. The osteoprogenitor cells from the bone marrow may also differentiate into the osteoblasts at a high rate when LIPUS is used. This will enhance the bone healing process and remodeling.

CONCLUSION

The use of low-intensity ultrasound system is a relatively new technology that has been proven to be safe and efficient in the treatment of acute fractures or in cases of non-union or delayed union. The effects at the cellular and molecular level demonstrate its efficacy.

A new global threat for the public safety: Zika virus

Simona Bicheru[1], Ion Ștefan[2], Marius Necșulescu[1], Diana Popescu[1], Lucia Ionescu[1], Gabriela Dumitrescu[1], Viorel Ordeanu[1,3]

Abstract: *Zika virus, the etiological agent of Zika fever, is transmitted by mosquitoes and has been affecting the South American continent starting with 2015. It was reported in several European countries, carried by the people who returned from Latin America, as reported by the health authorities in those countries. Today, according to the World Health Organization (WHO), the virus suspected to cause serious birth defects in the fetus has also been confirmed in 21 of the 55 countries of South America, but also in other states from Europe and North America. Zika virus is a single stranded positive sense RNA virus belonging to Flavivirus genus (family Flaviviridae) and was first identified in 1947 in Uganda rainforest Zika. The increased number of cases of microcephaly, in children from northern Brazil, suggested a connection with Zika virus, but it has not yet been proven. Also, the virus can be transmitted sexually and through blood or blood products. Diagnosis of the infection is made using Polymerase Chain Reaction (PCR). So far, there is no specific antiviral treatment or vaccine against the infection with Zika virus. The best form of prevention is to avoid mosquito bites. WHO has estimated that the spread of Zika virus, transmitted through mosquito bite, is "a global public health emergency". The priority is to protect pregnant women and to control the mosquitoes.*

Keywords: *Zika virus, Flaviviruses, microcephaly, Aedes aegypti, mosquitoes*

INTRODUCTION

Zika virus, the etiological agent of Zika fever, is transmitted by mosquitoes and has been affecting the South American continent starting 2015. It was reported in several European countries, carried by the people who returned from Latin America, as stated by the health authorities in those countries. Today, according to the World Health Organization (WHO), the virus suspected to cause serious birth defects in the fetus has also been confirmed in several countries from Europe: Great Britain, Italy, Netherlands, Portugal, Denmark and Switzerland.

Zika virus has been reported sporadically in Africa and Asia for several decades. Zika fever outbreaks were reported for the first time in 2007 (Yap island found in the Pacific Ocean), then in 2013 (French Polynesia). In 2015, outbreaks occurred in Africa (Cape Verde Islands) and South America (Brazil and Colombia). From here, Zika virus quickly spread to several countries in South and Central America and was finally reported in 21 countries of the region in early 2016. [1][2][3] On January 28, the World Health Organization announced that 3-4 million people in

---

[1] Military Medical Research Center, Bucharest

[2] Carol Davila Central University Emergency Military Hospital, Bucharest

[3] Carol Davila Universityof Medicine and Pharmacy, Bucharest

America could be infected with Zika virus in 2016. [4] On February 1, 2016, the WHO has estimated that the spread of Zika virus, transmitted through the bite of *Aedes aegypti* mosquito, is "a global public health emergency".

THE ETIOLOGICAL AGENT

Zika virus is a single stranded positive sense RNA virus belonging to *Flavivirus* genus (family *Flaviviridae*) and was first identified in 1947 in Uganda rainforest Zika. It is the etiological agent of Zika fever, a viral infectious disease transmitted by infected mosquitoes. [1][2][3]

SYMPTOMATOLOGY

The incubation period is 3-12 days after an infected mosquito bite. Most infections caused by Zika virus are asymptomatic (60-80%). Symptoms are usually mild and disappear within 2-7 days without severe complications or death. The main symptoms are rash (macular or a papular exanthema that initially appears on the face and then spreads throughout the body), moderate fever, arthralgia, myalgia, headache, non-purulent conjunctivitis with conjunctival hyperemia. Vertical transmission can occur during labor (in the viremic stage) or transplacentar. The increased number of microcephaly cases in children from northern Brazil suggested a connection with Zika virus, but it has not yet been proven. Also, the virus can be transmitted sexually and through blood or blood products. [1][2][3]

TRANSMISSION

Zika virus is transmitted by mosquitoes and was isolated from species of the genus *Aedes*, such as *A. aegypti* (Figure1), *A. africanus*, *A. apico argenteus*, *A. furcifer*, *A. hensilli*, *A. luciocephalus* and *A. vitattus*. Studies showed that the incubation period in mosquitoes is approximately 10 days [22]. Zika virus can be transmitted through interpersonal sexual contact and can cross the placenta, affecting the unborn fetus. An infected mother (in the viremic stage) can transmit the virus to the newborn at the time of labor. [24][25][26]

The vertebrate hosts of the virus are the monkeys.

Figure 1: Aedes aegypti (http://www.cdc.gov)

Before the current pandemic, which began in 2007, Zika virus rarely generated collateral infections in humans, even in areas recognized as highly enzootic [7]. In 2009, Brian Foy, a biologist at Colorado State University, reported the sexual transmission of the Zika virus. [13][14]. In 2015, the Zika virus was detected in the amniotic fluid of two pregnant women, indicating that it is possible to cross the placenta and cause infections in newborns. [4][34][4][5][35][36]

DISEASE

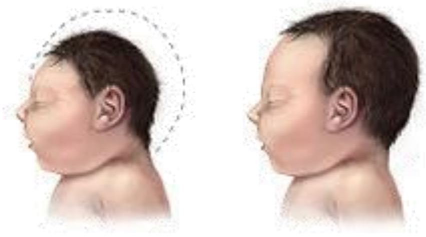
Zika virus infection symptoms normally include mild headache, maculopapular rash, fever, malaise, conjunctivitis and arthralgia. [33] The first thoroughly documented cases of Zika virus infections were described in 1964, being characterized by mild headache, progressing through maculopapular rash, fever and back pain. Within two or three days, the initial symptoms remitted, but the rash persisted. Patients with Zika fever are advised to rest and are prescribed fluids and acetaminophen, while aspirin and nonsteroidal anti-inflammatory drugs should be used only after Denga fever was ruled out, in order to reduce the risk of bleeding. [38]

COMPLICATIONS

Microcephaly. In December 2015, it was suspected that an infection of the fetus with Zika virus, transmitted transplacental, may cause microcephaly and brain damage. [5][34] Consequently, the European Centre for Disease Prevention and Control issued a comprehensive update on the possible association of the Zika virus with congenital microcephaly. [35] (Figure 2)

According to CDC Atlanta (Centers for Disease Control and PreventionUSA), "were reported cases of microcephaly defects in children of mothers who were infected with the Zika virus during pregnancy."

Figure 2. Comparison between a child with microcephaly (left) and a normal child (http://www.cdc.gov)



Zika viral infections were confirmed in several newborns with microcephaly; the number of microcephaly cases associated to Zika virus infection is unknown. [8][10][34]

On January 17, 2016 the Pan American Health Organization (PAHO), the Regional Office of the WHO, has recommended that its member states "establish and maintain the ability to detect and confirm cases of infection with Zika virus, given the increased number of congenital anomalies, Guillain-Barré syndrome and other neurological or autoimmune syndromes recorded in areas affected by Zika, to prepare healthcare facilities to respond to a possible increasing demand for specialized care for neurological syndromes and to strengthen prenatal care." [28][29]

DIAGNOSTIC

Zika virus is detected through PCR (gene amplification by Polymerase Chain Reaction). [15] [16] Since the viremic stage may be short, the WHO recommends that the RT-PCR testing should be done on the sera collected within 1 to 3 days after symptom onset or on the saliva or urine samples collected during the first 3 to 5 days after onset. [20][21][22][23]. Serological diagnosis can also be used by detection of specific IgM antibodies. Those appear towards the end of the first week of illness. [18]

Serological diagnosis can be difficult, given possible cross-reactions with other flaviviruses, for example the *Dengue* virus, *West Nile* virus or *Yellow Fever* virus. Zika commercial diagnostic tests are available at Euroimmun (www.euroimmun.com).

TREATMENT

Until present time, there is no specific antiviral treatment or vaccine available against Zika virus infection. The best form of prevention is to avoid mosquito bites.

Prophylaxis

The existence of mosquitoes and larval nests is an important risk factor for the infection with Zika virus. Disease prevention consists in decreasing the number of mosquitoes at source (elimination or modification of larval nests) and reducing contacts between these insects and humans. Those traveling to endemic areas should be informed on methods of protection against mosquito bites. These involve avoiding outdoor exposure at dusk and dawn, wearing clothes that cover as much exposed skin, using repellents, nets for beds impregnated with insecticide, accommodation in rooms with air conditioning and mosquito nets. It is also recommended emptying, cleaning and covering all containers that can collect water such as buckets, flower vases and tires in order to eliminate the places where mosquitoes can reproduce. During outbreak, health authorities can proceed to spray insecticide.

Vaccination

There are effective vaccines against several *Flaviviruses*. Vaccines against the *Yellow Fever* virus (antiamarilic), *Japanese encephalitis* and *Tick-Borneencephalitis* have been introduced from 1930, while the dengue fever vaccine just became available for use. [37]

According to Anthony Fauci, of the National Institute of Allergy and Infectious Diseases, attempts are made in order to obtain a Zika virus vaccine. [38] Researchers at the Research Center for Vaccines have extensive experience in obtaining vaccines against other viruses such as the Chikungunya and the Dengue fever virus. [38] Nikos Vasilakis, from the Center for Biodefense and Emerging Infectious Diseasesappreciated that getting the vaccine could take up to two years, but an effective vaccine for public use, approved by regulatory authorities, could be obtained in 10 – 12 years. [38][39][40][41]

EPIDEMIOLOGY

In 1947, scientists researching Yellow Fever revealed the onset of fever in a *Macaccus Rhesus* monkey located in a cage in the Zika Forest (Zika meaning "too high", in the Luganda language), near the Research Institute of Virology East Africa, in Entebbe, Uganda. The researchers have isolated from the monkey's serum a transmissible agent, which was first described in 1952 as the Zika virus [17] and was subsequently isolated in 1954 from a person in Nigeria. Since its discovery until 2007, rare cases of Zika virus infection were recorded in Africa and Southeast Asia. [40] In April 2007, the first outbreak outside Africa and Asia was declared on the island of Yap, in the Federated States of Micronesia; the cases were characterized by skin rash, conjunctivitis and pain, initially associated with Dengue, Chikungunya or Ross River disease. [41] However, the serum samples analyzed from patients in the acute phase of infection confirmed Zika virus infection. There have been 49 confirmed cases and 59 cases were disproved. There was no need for hospitalization and no deaths were reported. [42] Subsequently, outbreaks have appeared in Polynesia, Easter Island, the Cook Islands and New Caledonia. [5]

Starting April 2015, an epidemic broke out in Brazil with Zika virus (Figure 3) and has spread to South and Central America, the Caribbean, having a trend of global spread. In January 2016, CDC issued a level 2 travel alert for people traveling to affected areas (Table 1, Figure 4).

IMPLICATIONS FOR THE PUBLIC HEALTH

The WHO recommends that women planning to become pregnant should consult their physician before traveling to regions affected by the disease. [9][44] Governments and health agencies in the European Union, including UK and Ireland, as well as those in New Zealand, Canada, Colombia, Ecuador, El Salvador and Jamaica have issued similar travel warnings. Specific plans and measures were announced by authorities in Rio de Janeiro, Brazil, to prevent the spread of the Zika virus during the Olympic Games, taking place in this city, in 2016. [11][45][46]

According to CDC, Brazilian health authorities have reported more than 3,500 cases of microcephaly between October 2015 and January 2016. Some affected infants had a severe type of microcephaly, while others died.

These manifestations may be associated with Zika infection, occurred during pregnancy. Several studies are planned to assess the risks of the Zika virus infection during pregnancy. [45] In the worst affected regions in Brazil, about 1% of newborns are at risk for microcephaly. [46]

COMMENT

In humans, Zika virus causes an infectious disease called Zika fever, characterized by fever, headache, maculopapular rash, malaise, conjunctivitis, arthralgia etc.

The WHO has warned that the spread of Zika virus, transmitted by mosquitoes, is ''a global public health emergency'' and can be correlated with an increased number of newborns with congenital malformation recorded in Brazil last year.

WHO warns that Zika virus, transmitted mainly by mosquitoes, "explosively" spreads in South America, where in 2016 could be millions of cases. The priority is to protect pregnant women and to control the mosquito populations.

Medical experts are concerned about the very rapid transmission, over long distances of the virus with devastating consequences. From the confirmation of the presence of Zika virus, in May 2015, the virus has spread so far in 23 countries, including Brazil, Bolivia, Paraguay, Mexico, Venezuela and the epidemic continues to spread.

CONCLUSIONS

The World Health Organization has warned that the spread of Zika virus, transmitted by mosquitoes, is a

”global public health emergency”, which can be correlated with the increased number of newborns with congenital malformation recorded in Brazil last year and that the virus "explosively" spreads in South America, where in 2016 could be millions of cases.

Experts are concerned about the very rapid transmission, over long distances of the virus; the consequences can be devastating, and the priority is to protect pregnant women and to control the mosquito populations.

National health authorities are requested to take necessary measures for the prevention, diagnosis and treatment of Zika fever cases and to isolate import cases, in order to impede the spread of the disease.

Also, scientific research is needed in order to obtain an effective vaccine against Zika virus.

SYSTEMATIC REVIEW

Article received on January 12, 2015 and accepted for publishing on January19 2015.

Morphopatological and histochemical highlights in normal and varicose vein wall

Alina Condor[1], Caius Solovan[2], Liliana Vasile[2]

Abstract: *The nutrition of the venous wall appears to be an important factor in the vascular-fibrillar trophicity and in the dynamic of the extracellular matrix formation for the normal veins and, for the chronic venous ulcers of legs, on period of healing. Sequential biopsies were taken at various levels of venous wall of external and internal saphena in 16 cases presenting a chronic condition of legs venous system (35-58 years old patients, both sexes). 8 vein fragments with normal macroscopic appearance were also taken, in necropsy.*

These samples were analyzed using regular morphological methods and some histochemical reactions to reveal the glycogen, glycoproteins, and glycosaminoglycans substrates. There were been used the Gomori silver impregnation and orcein to expose some specific substrates like reticulin or elastin. Other staining methods, like Gomori trichrome, were used to differentiate the specific structures of the vein wall, were used to differentiate the specific structures of the vein wall.

A rich vascularization of normal and dilated vein wall could be remarked.Angiogenesis in vein wall and vasa vasorum changes as well as alcianophilic of vascular intima seem to be reactive and protective factors, depending on the applied therapeutic modalities. The veins are weak structures whose integrity depends on the thickness of the media and the support of neighboring structures.

INTRODUCTION

The emergence of varicosities it is supposed to be a consequence of defective development of venous wall and appears to be inherited. The proper nourishment of the venous walls appears to be an important factor in their trophicity. The incidence of varicose veins is about 1% of the adult population [5]. Both obesity and aging are involved as risk factors for emergence of defects in venous wall tissue support. The etiology and pathophysiology of varicose disease remains controversial. We emphasize the involvement of the following lesional links amid stasis hypoxia:

- Redistribution of microcirculation with arrangement in lobular aggregate of vessels in the superficial dermis;

- Areas of floride proliferation mimicking Kaposi's sarcoma (acro-angio-dermatitis), reticular dermis fibrosis and massive deposits of hemosiderin, degeneration of dermal fibroblasts (senescent fibroblasts converted by modulation into myofibroblasts having a role in periulceros tegument retraction) to extended tissue matrix lysis;

---

[1] Department of Dermatology, Emergency Military Hospital, Timișoara, Romania
[2] Victor BabeșUniversity of Medicine and Pharmacy, Faculty of Medicine, Timișoara

-Outbreaks of fat necrosis concomitant with a proliferative-alternative response of adjacent epidermal, hyper parakeratosis and orthokeratosis and pseudoepitheliomatous hyperplasia.

The presence of lytic degradative tisular factors (metalloproteinase) and activation of monocito-macrofagic system induced degradation of the basal membrane and chronic venous ulcers.

Morpho-histochemical current study aims to deepen the importance of veins wall nutrition in normal and dilated veins. It also envisages the re-active participation of supra-adjacent dermo-epidermal tissue, the possible influence on vessel permeability and vasoprotective or anticoagulant medication used in selected cases in the study.

MATERIALS AND METHODS

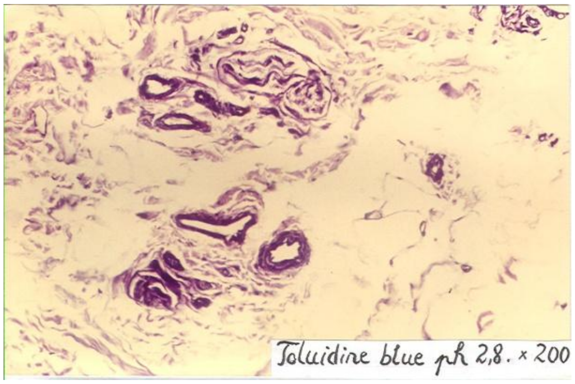
16 biopsies were taken sequentially from the varicose saphenous in areas of dilated vein (12 cases) and in the vicinity of shank chronic venous ulcer (4 cases); Saphenous fragments from normal vein were collected at necropsy (8 cases). Cases have included both sexes. The selected cases were with at least 5 years of disease duration and the type of treatment was also considered.

Patients in the study were selected from the inmates in Department of Surgery of Military Emergency Hospital and University Clinic of Dermatology in Timisoara.

Processing of samples was performed at the Department of Histology of Medicine and Pharmacy University in Timisoara by usual histological techniques: all samples were fixed in 10% formalin, buffered formalin, AFA fixator (Alcohol - Formaline - Acetic acid), paraffin inclusionated, sectioned at 5 µm, then colored by hematoxylin-eosin. For histochemical study, there were been applied reactions PAS (blue Alcian (BA)) and salivary amylase-PAS (Alcian blue used at pH 2.8 and pH 0.5); blue toluidine (BT) at pH 5 and pH 2.8; it was used Gomori silver impregnation for reticulin and it was also used trichrome Gomori reaction.

Orcein staining method was used to expose elastin.

Figure 1: Lipodermatosclerosis (*toluidine blue, pH 2,8, ×200*)

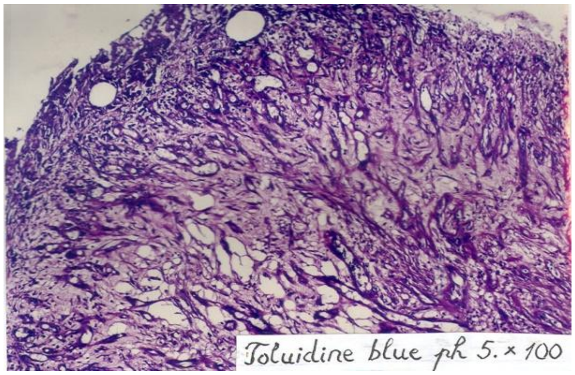


RESULTS

In all examined cases, the wall of external and internal saphenous veins was well vascularized, containing arterioles, venules, capillaries in musculo-fiber media. Constant, parietal capillaries from vasa vasorum were not flattened. In varicose veins adventitia, in small and medium vessels, were frequently found leukocytic marginations and acidophilic deposits and PAS positive, weak metachromatic fibrin (Figure 1).

Fibrin sleeves were also observed in the wall vessels of varicose veins in which angiogenesis is very marked. For AT, were remarked weak metachromatic perivascular sheaths, at pH 5 and chromophobe tissue matrix of dilated veins sheaths, at pH 2.8. Orthochromatic of nuclei allows observing the phenomenon of leukocytes margination (mostly lymphocytes) in the parietal small and medium vessels up next to intima, for both pH used (Figure 2).

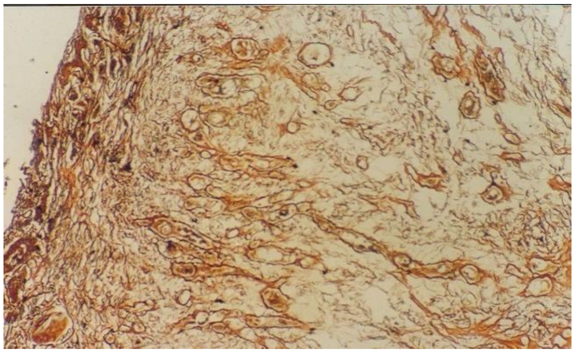
Figure 2: Perivascular sheaths and parietal leucocytes margination in small and medium sized vessels, close to venous intima (*toluidine blue, pH 5, ×100*)



In all methods used in this study, the average media of varicose veins appears thickened through a rich smooth muscle proliferation (HE col., Gomori trichrome col.), with weak orceinic material fragmented through the wall layers (Orcein col.). There were observed fake elastic limitations, fragmented, disorganized (orcein, Gomori trichrome). In one case of all cases examined, using combined staining AA-PAS, which stands under anticoagulant therapy, an edemic intima and hyperplasia were observed, with fundamental alcianophilic substance (FS) and somewhere with deposits PAS positive as a rich interstitial material PAS positive all that pushing aside and cleaving muscle layers of the vascular media. Other intimal changes reported in our study are notches and extensive fibrosis, miointima hyperplasia of saphenous varicose veins.

Alcianophilic fibrillar material with reticular disposition is perivascular distinguished in the neo-capillaries that invade from adventitia media. Silver impregnation for reticulin (Figure 3) shows neo-formation basic membrane by budding vasa vasorum from adventitia to media to decline to extinction the reticulin network of media muscular interstice and vasa vasorum walls.

Figure 3. Reactive angiogenesis in variceal venous wall (*silver impregnation, ×200*)



The phenomenon seems to affect 2/3 of external walls of the dilated veins. In neighboring dermal and epidermal tissue and in the perivascular support appear lesions like: lipodermatosclerosis, fibrosis and perivascular fibrin deposits and interstitial fragmentation of elastic fibers in the deep of dermis, tinctorial variations of epidermal cells cytoplasm for which an accumulation of PAS positive material could be noted and cemented SF was PAS reactive. For silver impregnation, the dermal epidermal limit appears fibrillary fine, thinner than the normal appearance.

DISCUSSIONS

The changes of vein wall tissue architectural pattern take place simultaneously with the progression of venous distension in varicose vein disease. It is noticed an important reaction of vessels in vasa vasorum which angiomatosic proliferate, invading media, almost to intima, leading to muscular media hypertrophy [5]. Vascular proliferation can be reactive to miointima hyperplasia and to varicose wall media. Chronic shank venous ulcer it is possible to occur, in time.

Thus, as a reaction to increased venous pressure in a vein much thickened, on account of media and intima and hence to the shank edema, fibrin sleeves occur, those may inhibit the angiogenesis [4]. However, it is created a protection against increased venous additional pressure with a possible role in causing tisular ischemia [6][8].

Fibrin sleeves were found around the capillaries of the dermis in lipodermatosclerosis. Massive deposits of fibrin are involved in elastin fragmentation of the deep dermis and in elastic limitations of vascular walls. Vasa vasorum angiomatosis proliferate in invading varicose vein media. Since 1992, "leukocyte sleeve" was reported as a response to chronic stasis. White blood cells can accumulate in the lumen of capillary and venular, increasing perivascular resistance.

Activated endothelium becomes thrombogenic surface (via tissue factor secreted by endotheliocyte: factor VIIa, factor X-Xa). Simultaneously, activated endotheliocyte was involved in angiogenic peptide synthesis, stimulating neovascularization of dermis and ectasiated venous walls. Tissue anoxia and ulceration is installed.

Consistent with the cited literature, we found also an increased number of capillaries in the skin of patients with venous hypertension in the lower limbs.

Wall vessels are the only ones bringing oxygenated blood, draining interstitial fluid and extravasated colloidal material [7][1][3]. This explains the rapid drainage and metastasis of tumor cells via veins and lymphatics with rich vascularity, having intraparietal capillaries opened.

Adventitial enriched positive PAS material, periadventitial and intraparietal, is represented by fibrin, and also by a macromolecular glycoprotein substrate containing laminin, fibronectin, tenascin detected by immunocytochemical investigations by some cited authors [2][5].

So we can correlate the "leukocytic margination" phenomenon in vasa vasorum and intraparietal vessels with depolymerization of SF tissue more evident in the 2/3 of external portion of the varicose venous wall.

The histochemical reactions used in our study, draw attention to the changes in the three fibrillar component. In varicose veins (dilated segments thereof) we found a quantitative increase of mature collagen fibers and reticulin, morpho-histochemical revealed, with a decrease and fragmentation of elastic fibers in the dilated walls. Together with the degradation of elastin, reticulin network growth can be an important factor in the parietal frailty in shank venous insufficiency evolution.

Marked alcianophilia of intima (AA pH 2.8) calls attention to presence at this level of complex carbohydrates with carboxyl groups and hydroxyl radicals in position of vic-glycol (sialic acid and hyaluronic acid) which act as intima hydrator, but may decrease macromolecular complexes stability of glycoproteins (with increase of sialic acid amount).

Sialic acid carboxyl groups and other substances not yet identified are responsible for basophilia and metacromazia of certain reticulin networks and basement membranes. The enriched PAS positive interstitial material in dilated vessels media is favorable to reticulin collagenization (gradual multiplication of preexistent collagen fibers in a glycoprotein matrix apparently unchanged).

Reticulin collagenization occurs when the hydroxyl group probably belonging to hydroxyproline and hydroxylysine achieve the appropriate concentration [9].

In the cases we investigated, collagenization is conducted in a glycoprotein reticulin dominant matrix (in the external 2/3 dilated vein wall), progressively decreasing toward intima, simultaneously decreasing nourishment intake by vessels of the vein wall fibrosing.

CONCLUSIONS

Morpho-histochemical methods draw attention to the complex of walls reshuffles of venous leg during chronic venous insufficiency. There are being considered the three coats of veins in that appear to be successive lesional patterns: mio-intimal hyperplasia, medial muscle hypertrophy, reactive angiogenesis, lipodermatosclerosis, collagenization of medial muscle.

The chronic venous stasis can be quantified by morphological parameters: mio-intimal hyperplasia, medial muscle hypertrophy, reactive angiogenesis, lipodermatosclerosis, collagenization of medial muscle. The prolonged venous hypertension modifies both the local microcirculation conditions and selecting of fibril-forming cells, triggering the evolution of chronic venous ulcers.

Expandable stents in digestive pathology – present use in an emergency hospital

Mădălina Ilie[1], Vasile Șandru[1], Cristian Nedelcu[1], Bogdan Popa[1], Gabriel Constantinescu[1]

Abstract: *Introduction: Self expandable metal stents (SEMS) are developed lately, as an effective and safe, less invasive alternative of surgery for the treatment of malignant intestinal/biliary obstruction. Recently, SEMS are also introduced in benign pathology.*
Aim: The aim of this presentation is to report a retrospective analysis of the total number of SEMS placed for esophageal, enteral, colorectal and biliary obstruction during the last 3 years in Clinical Emergency Hospital Bucharest, as well to review the literature published on this issue.
Methods: Between 2013-2015 in Clinical Emergency Hospital Bucharest, we have placed: 232 esophageal stents, 23 enteral stents, 5 colonic stents and 75 biliary stents under radiologic guidance. The main parameters followed were represented by: sex, age, grades of obstruction, stent diameter and type, immediate and late complications and survival rate.
Results: Regarding the esophageal stenting, most of the indications were malignant obstruction (155 cases of esophageal cancer and 30 cases of extrinsic compression), but also for esophageal fistula, peptic stenosis and even traumatic esophageal rupture. The majority of the enteral and colonic stents were inserted for malignant obstructions, having only 2 cases with benign obstructions. This is also the case for biliary stenting, were most of the indications were represented by pancreatic cancer. Technical and clinical success rates were approximately 92% and 80%, respectively. There were no major complications of perforation, bleeding, or death.
Conclusions: SEMS insertion can be performed safely, with minimal complications and hospitalization allowing the restart of oral feeding and improvement of nutritional status for the digestive obstruction or jaundice disappearance in case of biliary obstruction. It represents the first option for unresectable digestive/biliary malignant obstruction.

Keywords: *expandable stents, malignant obstruction, fistula, stenosis.*

INTRODUCTION

Over the past decades, the endoscopic approach for palliation of malignant obstruction has overcome the use of percutaneous approach. The options for endoscopic stenting are either self-expandable metal stents (SEMS) or plastic stents (PS). PSs are composed of polyethylene, polyurethane, or Teflon,whereas SEMSs are made of various metal alloys that are constructed to achieve adequate radial expandable force without sacrificing flexibility and conformability to the duct [1].SEMSs can be either uncovered or covered with material to prevent tumour ingrowths. Recently, uncovered self-expandable biodegradable stents were added to this portfolio [2].

The ideal stent have to be pliable, atraumatic but also forceful to maintain patency and position in the

---

[1] Clinical Emergency Hospital Bucharest

lumen. However, stents should also be easily removable and without any risk for benign hyperplastic or malignant tumor ingrowths or overgrowth.

The current guidelines from the American Society for Gastrointestinal Endoscopyfor distal malignant biliary obstruction recommend either SEMSs or PSs, with PSs preferred in cases of distant metastasis and short life expectancy. However, studies have shown that although PSs are less expensive, metal stents have better drainage and longer patency,with recent data showing they are more cost-effective [3][4].

METHODS

We have done a retrospective, non-randomized study between 2013-2015 in Clinical Emergency Hospital Bucharest. We have placed: 232 esophageal stents, 23 enteral stents, 5 colonic stents and 75 biliary stents under radiologic guidance. The main parameters followed were represented by: sex, age, grades of obstruction, stent diameter and type, immediate and late complications and survival rate. We had exclusion criteria: an INR more than 3 and an estimated survival time less than 3 weeks. Regarding the dysphagia we have used Mellow and Pinkas's scale.

0 = able to eat normal diet / no dysphagia.
1 = able to swallow some solid foods
2 = able to swallow only semi solid foods
3 = able to swallow liquids only
4 = unable to swallow anything / total dysphagia

We have used most the nitinol stents (alloy of nickel and titanium), because of their ability to conform to anatomical angulations and the latter for their removability.

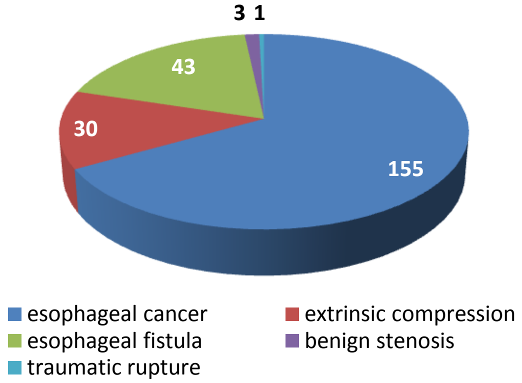
RESULTS

More than 65% of the patients were male with age varying between 49 and 83 years old.

Regarding the esophageal stenting we have placed in Clinical Emergency Hospital Bucharest, 232 oesophageal stents for the following indications (Figure 1):

-155 cases of esophageal cancer
-30 cases of extrinsic compression
-43 cases of esophageal fistula
- 3 cases of benign stenosis
- 1 case of traumatic rupture of the esophageal wall

Figure 1: Graphic representation of esophageal stenting indications



The majority of the cases (> 50 %) have unresectable disease at the time of diagnosis, either because of distant metastases or unsuitable candidates for surgical resection.

The aims of palliative therapy are to ameliorate symptoms of dysphagia, treat complications, maintain oral intake, minimize hospital stay, relieve pain and ultimately improve their quality of life.

We have used: totally covered SEMS or partially covered SEMS. Fully covered stents are more prone to stent migration; removable and theoretically may be more suitable for benign strictures/fistula whereas partially covered stents have a small portion of exposed bare metal in both proximal and distal ends to allow embedding into the oesophageal wall, which helps to decrease stent migration. The uncovered portion of the partially covered stents allows embedding and anchoring. No differences in survival rates were observed between these two types [5].

The techniques used for inserting the stent were: OTG – over the guidewire (most of the cases) or TTS (through the stent) both under radiologic view. At the beginning the lesion is visualized under endoscopy (Figure 2A – oesophageal fistula) and upper end is marked by injection of contrast agent into the submucosa (Figure 2B).

It is very important for the marking to be done internally and not to put external marks that may move during the procedure. The stents are mounted in a preloaded constrained position on a delivery catheter.

A guide wire is passed through the lumen of the catheter (Figure 2C), and when the wire has been advanced beyond the obstruction, the stent is passed over it and positioned across the stricture with the upper end at the position of the internal contrast mark (Figure 2 D, E, F).

Figure 2A: Esophageal fistula

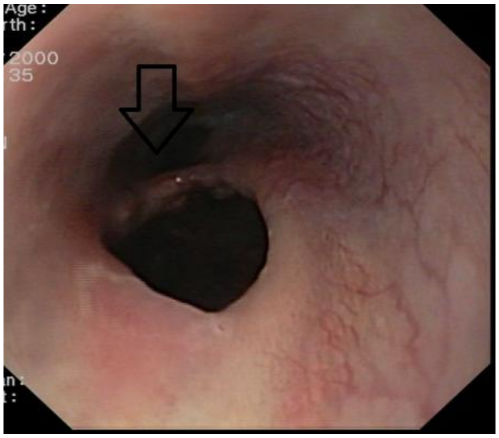


Figure 2B: Contrast injection

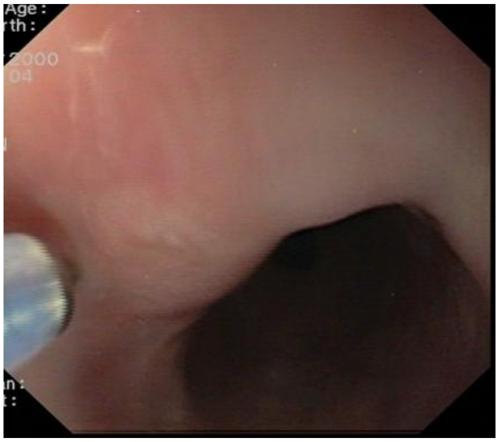

The immediate complications encountered were: retrosternal pain (60%), alleviated after antalgics, stent migration while as late complications we had: food impactation (7%),fibrous tissue invasion (4%), tumoral invasion (5%),uncovered fistula and upper GI bleeding.

Figure 2C: Guidewire insertion

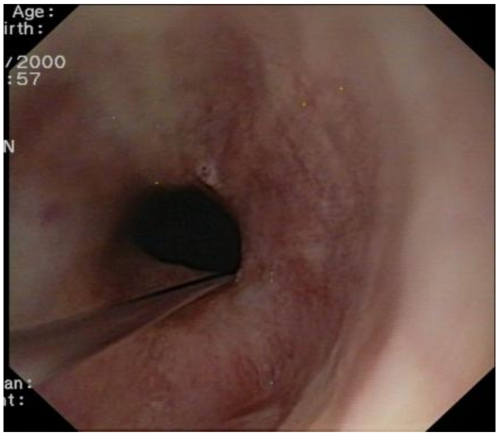

Figure 2D: Stent deployment

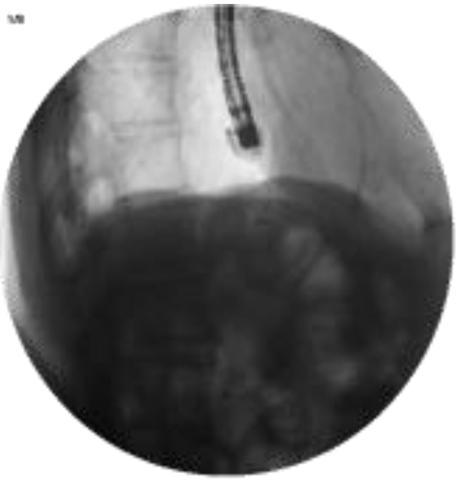

Figure 2E: Stent view on RX

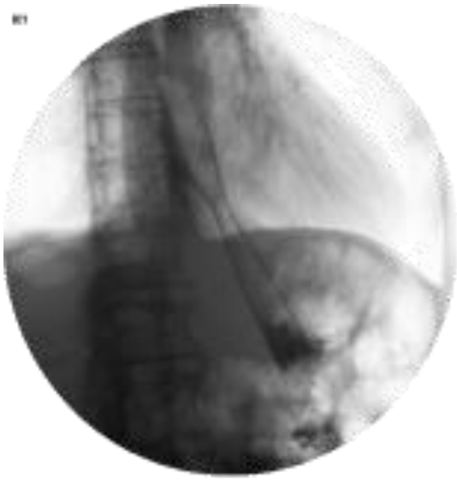
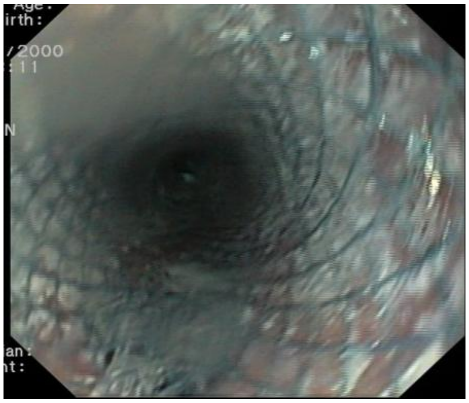


Regarding the enteral stenting we had 23 total cases: 21 for malignant extrinsic compression and 2 cases for benign stenosis. The technique used was TTS (through the scope) with low rate of complications.

Figure 2F: Stent under endoscopy view



A specific situation was double stenting, both enteral and biliary (Figure 3 A, B), especially in pancreatic head malignancies with obstructive components.

Figure 3A: Double stenting (enteral+biliary)

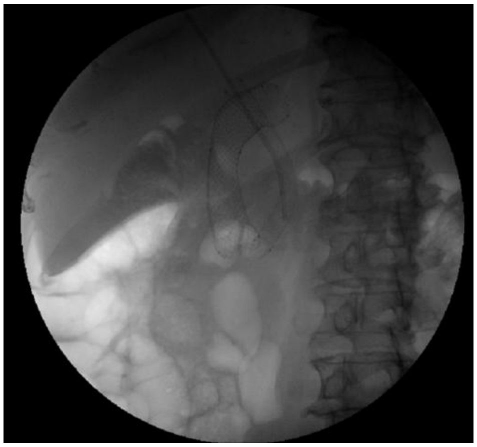


Figure 3B: Enteral stent-endoscopic view

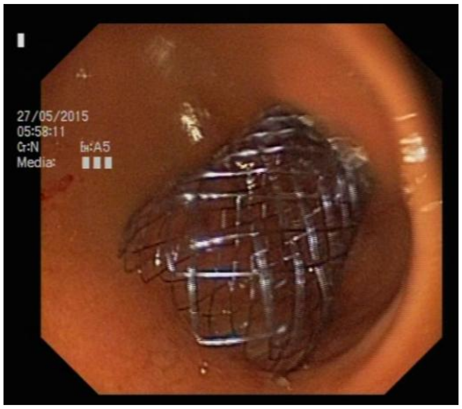
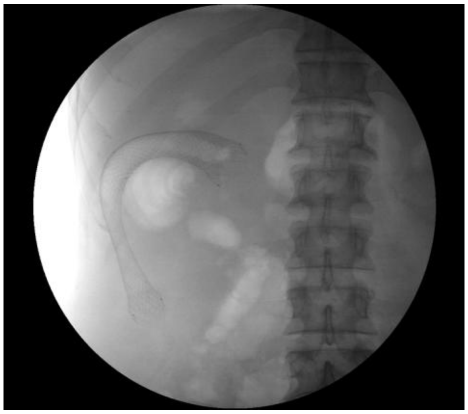


Colonic SEMS placement is recommended as the preferred treatment for palliation of malignant colonic obstruction, except in patients treated or considered for treatment with antiangiogenic drugs [6]. Stent insertion may be considered as an alternative to emergency surgery in those who have an increased risk of postoperative mortality. We have placed only 5 colonic stents (Figure 4), mainly because of ease of accessibility to the surgical service in our hospital.

Figure 4: Colonic stent



In case of biliary stenting we have inserted 73 stents for malignant obstruction (approx. 60% pancreatic cancer) and only 2 for benign obstruction (chronic pancreatitis). SEMSs range from 4 to 12 cm in length with diameters when expanded ranging from 6 to 10 mm.

Self-expanding metal stents (SEMSs) are built from different metal alloys, mainly nitinol, that are used to achieve adequate radial expansive force leading to increased patency duration and reduced recurrent obstruction.

SEMSs are preloaded in an outer sheath with a diameter of 8.5F or smaller, allowing use with a therapeutic duodenoscope. After placement in the duct, the outer sheath is withdrawn, allowing the stent to expand (Figures 5A, B, C).

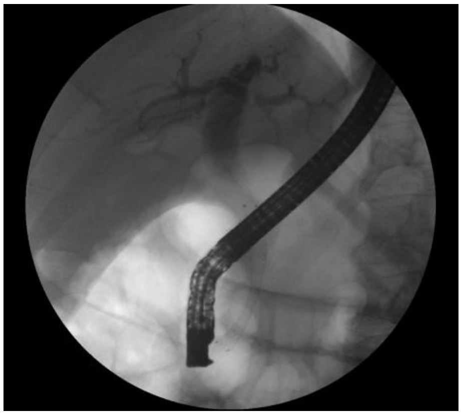
SEMSs can be covered, partially covered, or uncovered.

Partially or totally covered SEMSs can be repositioned or fully removed, reduce the rate of stent occlusion but they have risk of cholecystitis because of involvement of the cystic duct orifice). Acute cholecystitis may occur in as many as 10% of patients with intact gallbladders after placement of a covered SEMS across the cystic duct. In opposition, uncovered SEMS migrate less but have risk of tumor ingrowths [3].

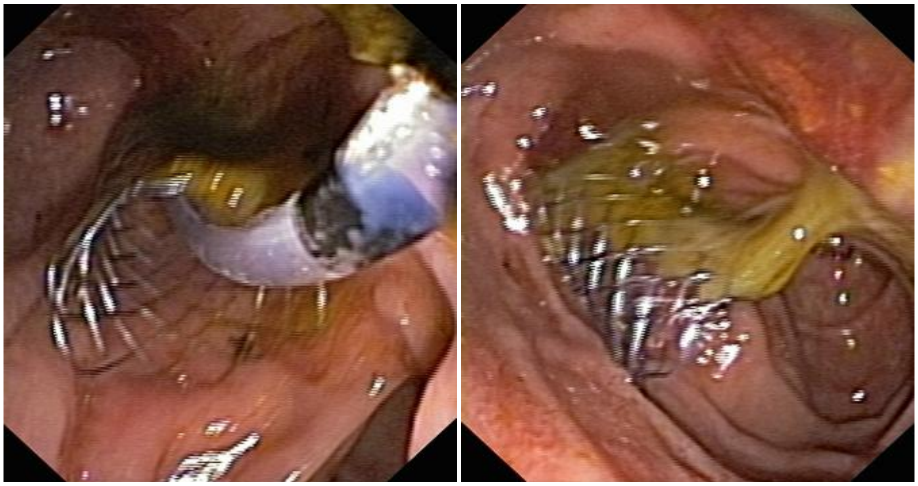
SEMS insertion at patients with malignant biliary obstruction palliate jaundice, anorexia and most important help the initiation of chemotherapy that otherwise would be contraindicated.

Initial insertion of a plastic stent is most cost-effective if patient life expectancy is shorter than 4 months; if it is longer than 4 months then initial insertion of a SEMS is more cost-effective.

Figure 5A: Distal biliary obstruction; stent insertion radiologic view



Figures 5B, 5C: Endoscopic views



CONCLUSIONS

SEMS represents a very useful alterative, with minimal complications to classic surgery for palliation of unresectable digestive/biliary malignant obstruction. With the current development and applications of new materials and technologies, the future of stenting is evolving.

New trends include drug-eluting stents, biodegradable biliary/esophageal stent and the use of biodegradable polymers for local drug delivery, having also curative aim [7] . Radiation therapy, a cornerstone of treatment for malignant disease of the esophagus, may also be administered in conjunction with placement of esophageal endoprosthetics [8].

Regarding the biliary malignant obstruction, we recommend that SEMSs should be the first option because they have better patency, a lower occlusion rate, less need for reintervention, and fewer adverse events than plastic stents.

In conclusion, expandable metal stent placement is a very effective way of re-establishing luminal patency with negligible complications for an expert endoscopist.

Hepatic hydatid cysts

Cătălina Diaconu[1], Mădălina Ilie[2,3], Alexandru L. Chiotoroiu[3], Laura Voicu[1], Daniel O. Costache[1], Raluca S. Costache[1,2]

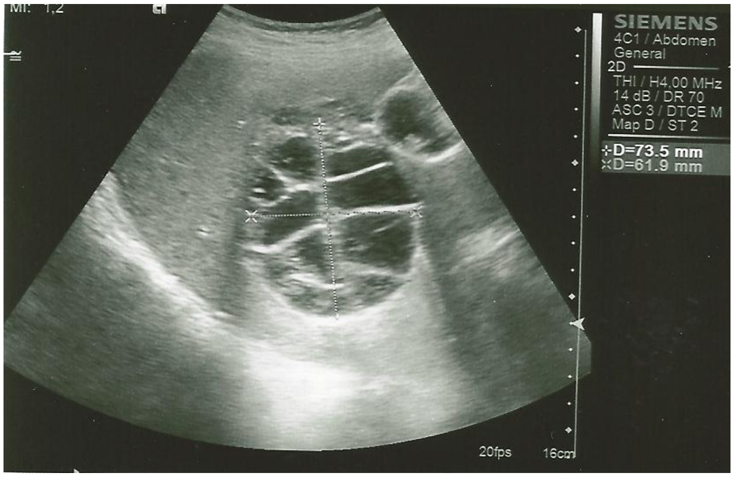
43 years old man presented with recently installed abdominal pain localized in the hypocondrium and epigastrium associated with jaundice and pruritus.

The patient's history included operated bilateral inguinal hernia. Physical examination yielded jaundice, normal aspect of postoperative scars in the inguinal fossae (left and right), pain in the hypocondrium and epigastrium, no guarding, rebound or bruits were found.

Laboratory findings reveal leukocytosis with eosinophilia, hepatic cytolisis (alanine aminotransferase = 219 U/L), hyperbilirubinemia with a higher conjugated bilirubin (total bilirubin=6.01mg/dL, conjugated bilirubin=4.7mg/dL).

Ultrasonography reveals a round transonic image of 7/6cm localized in the IV and VIII segment, with septa that suggests liver hydatid cyst, hyperechoic image of 9mm (hydatid cyst) and a 9mm gallbladder polyp. Computed tomography shows hepatomegaly with a cystic multiseptate image in the IVth segment of 8.5 cm.

Under treatment against pain, proton pump inhibitor, hydratation and regime during hospitalization the symptoms disappear. However the hepatic cytolysis worsens with the progressive growth of alanine aminotransferase to values of 916 U/L, hence anti-helminthic treatment is delayed.



Enchinococcal infection caused by the larval form of *Echinococcus granulosus* remains an important health issue worldwide. Hepatic hydatid cyst is the most frequently encountered form (50-93% of the cases) and left untreated these grow and lead to: developing fistulae in adjacent organs, rupture in the peritoneal cavity, produce daughter cysts or dye (rarely)[1]. Clinical manifestations appear after the cyst is larger than 10cm in diameter and only a third of the patients experience symptoms.

Even though biological finding are nonspecific, elevated bilirubin and alkaline phosphatase may appear. Leukocytosis may appear due to infection of the cyst and eosinophilia is present only in a quarter of patients [2].

Despite the fact that ultrasonography remains the main pillar in the diagnosis of the disease, computed tomography and serology help improve the accuracy of diagnosing liver hydatidosis. WHO Ultrasound classification of echinococcal cysts helps establish the treatment: 1 (unilocular, anechoic cyst with double line sign), 2 (multiseptate honey comb cyst), 3a (cyst with detached membranes), 3b (cyst with daughter cysts in solid matrix), 4 (heterogenous contents and no daughter cysts) and 5 (solid plus calcified wall). CE4 and 5 are inactive.

On the other hand Gharbi classification also divides in 5 types: type I cysts consist of pure fluid; type II has a fluid collection with a split wall; type III cysts contain daughter cysts (with or without degenerated solid material); type IV has a heterogeneous echo pattern; and type V has a calcified wall. Therefore our case presents a hepatic hydatid cyst stage CE2 after WHO classification and type III after Gharbi classification.

Uncomplicated and small lesions (under 5cm) CE1,2 and 3 can be treated with oral albendazole (10-15mg/kg/day) and close monitoring. However, large CE1 and CE3 cysts need treatment with both albendazole and PAIR (percutaneous aspiration, introduction of scolicide and reaspiration), performed after initiation of albendazole.

Primary surgical treatment has been replaced with less invasive methods since the relapse rate can reach 20%. In patients with complicated cysts, surgery is the treatment of choice. CE4 and 5 only need to be monitored [1][3].

More than simple hepatic cysts

Daniela Tabacelia[1], Mădălina Ilie[1], Alina Constantin[1], Anca Macovei Oprescu[2], Gabriel Constantinescu[1]

Abstract: *Caroli diseaseis a rare congenital disorder that classically causes saccular dilatation of the bile ducts. The complications of Caroli include choledochal cysts with recurrent cholangitis, abscess formation, septicaemia, intrahepatic lithiasis and amyloidosis.We report a rare case of a young female with Caroli disease pointing out the intrahepatic lithiasis as a rare complication of the disease.*

Learning points

- *Caroli disease is an uncommon condition that should be considered in the differential diagnosis of hepatic essential cysts.*
- *Clinically, it is characterized of recurrent episodes of fever and pain.*

The correct and early diagnostic is important because of the different complications and treatment unlike the essential hepatic cysts.

Keywords: *Caroli disease, intrahepatic lithiasis, endoscopic retrograde cholangiopancreatography*.

CASE REPORT

A 28 years old female presented to the emergency department with abdominal pain and fever after an ERCP procedure performed 2 weeks ago. From her disease history we retain an acute pancreatitis that was classified Balthazar B, one year ago, assumed to be caused by biliary main duct lithiasis; at that moment her initial biology showed ASAT 156U/L, ALAT 126U/L, lipase 2,398U/L, bilirubin 32 mmol/l and white cells 14,590/mmc; there was no sign of complication (acute cholangitis) that would have required a surgical treatment in emergency. Her family history was inconclusive for any specific digestive condition.

In our hospital, on physical examination her body temperature was reaching 38^0C, the heart rate 110 bpm, and blood pressure 110/70mmHg; on palpation she presented mild tenderness on epigastric and right quadrant; the usual blood tests showed white cell count with neutrophils raised, hepatic cytolysis and cholestasis until 5 times normal value. Next step was performing an abdominal ultrasound which revealed hepatic cysts (dilation of intrahepatic bile ducts) with liver hyperechoic images with acoustic shadow suggestive of intrahepatic lithiasis (Figures 1 A and B). A CT scan and a MRI were performed and revealed a normal pancreas without Wirsung dilatation, the biliary main duct with a 7 mm diameter without stones inside, and normal gall bladder without signs of cholecystitis but with beaded intrahepatic biliary duct dilatation until 18 mm alternated with normal caliber ducts with numerous images of stones inside with a 12 mm maxim diameter. The dilated biliary canaliculi wall presented signs of cholangitis. All clinical and paraclinical data were typical for a Caroli disease with intrahepatic lithiasis and secondary cholangitis. The patient received treatment with urso-deoxy cholic acid (UDCA), antibiotics, anti-inflammatory drugs and pain medication followed by the resolution of the inflammatory episode.

Figure 1A

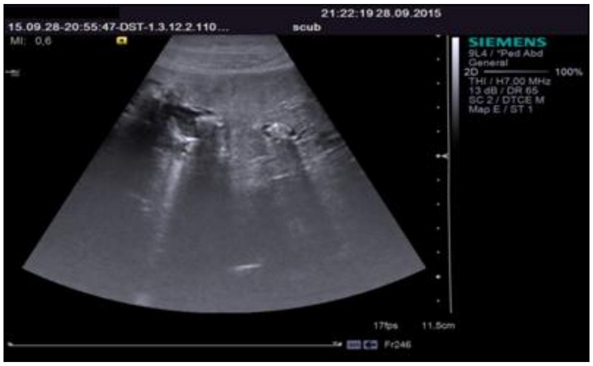

Figure 1B: Abdominal ultrasound revealing hepatic cysts with intrahepatic lithiasis

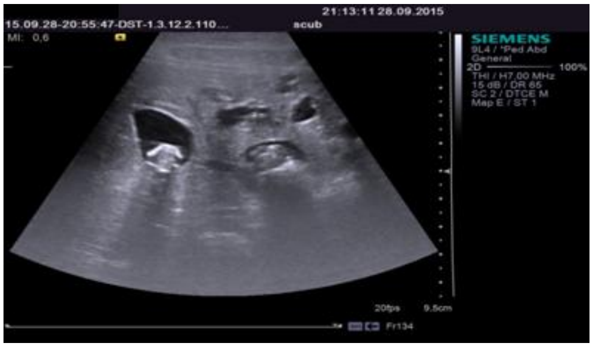

DISCUSSION

The hallmark of Caroli disease is intrahepatic duct dilatation [1]. Patients with Caroli disease are usually presenting to the hospital, when they develop complications as the result of biliary stasis, which leads to stone formation and infection. The stones are brown pigmented stones, composed of inspissated bile[1].

Caroli disease has two forms, one associated with congenital hepatic fibrosis and a simpler form occurring alone. The former, called Caroli's syndrome is associated with portal hypertension, and it's complications including splenomegaly, hematemesis and melena. Caroli disease is also associated with liver failure and polycystic kidney disease. The cause appears to be genetic; the simple form is an autosomal dominant trait while the complex form is an autosomal recessive trait.[2] Females are more prone to Caroli disease than males.[2] Family history may include kidney and liver disease due to the link between Caroli Disease and ARPKD (Autosomal recessive polycystic kidney disease). The symptoms include fever, intermittent abdominal pain, and hepatomegaly. Occasionally jaundice occurs.[3] Laboratory tests indicate cholestasis and hepatocytolysis associated with an inflammatory syndrome in the acute stages.

Caroli disease usually occurs in the presence of other diseases, such as autosomal recessive polycystic kidney disease, cholangitis, gallstones, biliary abscess, septicemia, liver cirrhosis, renal failure, and cholangiocarcinoma (7% affected).[2] People with Caroli disease are 100 times more at risk for cholangiocarcinoma than the general population.[3] Modern imaging techniques allow the diagnosis to be made more easily and without invasive imaging of the biliary tree.[4] Abdominal ultrasound can detect saccular or fusiform dilation of the bile ducts. Images taken by CT-scan or MRI will show enlarged intrahepatic (in the liver) bile ducts due to ectasia; cholangiography is the best approach to show the enlarged bile ducts as a result of Caroli disease.

The treatment of Caroli's disease depends on the clinical features and the location of the biliary abnormalities. Cholangitis is treated with appropriate antibiotics. In case of intrahepatic cholelithiasis litholytic therapy with urso-deoxy cholic acid (UDCA) is indicated[5]. When the ductal abnormalities are localized to one lobe, lobectomy relieves symptoms and appears to remove the risk of malignancy. In case of diffuse involvements of both lobes of liver, treatment options include conservative management, endoscopic therapy (sphincterotomy for clearance of intra-hepatic stone), internal biliary bypass procedures and in carefully selected cases liver transplantation[5].

Nutritional approach in late gastric stenosis after gastric sleeve

Adina Mazilu[1]

INTRODUCTION

Laparoscopic gastric sleeve(LGS) is a very frequent used procedure nowadays in Romania, with more than 100,000 reported patients operated until now, the most part of patients being operated in private settings. It is a simple and efficient procedure, less expensive than gastric by-pass, with fewer complications, but can reduce obesity complications almost as well as gastric by-pass. Indications for this type of surgery are:

- Body Mass Index is greater than 40 kg/m^2 or between 35-40 kg/m^2 and patient has significant pathology that may benefit from weight loss-like diabetes, hypertension
- Severe co morbidities (cardiac, pulmonary, liver disease)
- Advanced age at time of operation
- Inflammatory bowel disease (Crohn's disease)
- Patient uses chronic medications (anti-inflammatory or immunosupressive)
- Need for continued surveillance of the stomach (that couldn't be evaluated after a gastric bypass)
- Severely enlarged liver found during the operation
- Severe adhesions or scarring to the bowel found during the operation
- Any combination of the above that significantly increases the patient's anesthetic or surgical risk

LGS may be used also combined with gastric by-pass done at 12-18 months after LGS, when anesthesia is less risky and liver has reduced diameters.

Acute complications are represented by hemorrhage reported in 1-6% of cases and gastric leaks in up to 5% in the immediate period after operation [1]. Gastric stenosis has a 0 to 4 % rate of appearance for this type of operation[4]. Most cases can be solved by endoscopic dilation with balloons;however some cases need to be converted to gastric by-pass.

In an article from 2014,in a study done on 565 patients, the incidence of complications was relatively low- the authors[2] reported in 7.79% of patients infarcts of the posterior pole of the spleen, 1.42% gastric fistulas in the His angle region, with 5 deaths among these patients – 3 due to septic complications in the course of fistula, 1 due to encephalopathy and 1 as a result of myocardial infarction.

Chronic complications include strictures, malnutrition and GERD. Chronic strictures usually require further intervention. Endoscopic dilatation is an useful tool used for short segment stenosis. Successive treatments in 4 to 6weeks interval are adequate to treat stricture and ameliorate patient symptoms. In contrast, long segment stenosis and failure of endoscopic management demands a surgical intervention – laparoscopic or open seromyotomy or conversion to Roux-en-Y gastric bypass. Parikh and colleagues reported an incidence of 3.5% of symptomatic stenosis following LGS in their series of

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

230 patients; 2 patients required conversion to a Roux-en-Y gastric bypass owing to failure of endoscopic management.

In a recent study by Gehrer and colleagues[3], the prevalence of vitamin B12, vitamin D, folate, iron and zinc deficiency were reported to be 3%, 23%, 3%, 3% and 14%, respectively, after LGS In general, these investigators found micronutrient deficiencies to be less prevalent after LGS than Roux-en-Y gastric bypass; however, folate deficiency was slightly more common after LSG than Roux-en-Y gastric bypass (22% vs. 12%).

CLINICAL CASE

Our patient, a 25 years girl operated – LSG-1 year before, presented with severe malnutrition and dehydration, associating also hypokaliemia. She has been vomiting at least 4 times a day during the past 6 months and she lost almost 100 kg in 1 year (from 130 Kg, 167 cm to 37 Kg at admittance). She has done upper endoscopy 10 days ago and dilation of gastric stricture was not possible. She was told she needed surgical intervention after gaining 10 kg.

She was very pale, with brittle hair and dry skin, with Bichat's sign positive, hypotensive – 70/50 mmHg, tachycardic and refused admittance even if she was explained that she had a very high risk of death. She agreed to come and stay in hospital after solving the problems for her job. As she associated hypokaliemia we tried to correct it with 20 mEq of kalium in saline, but patient reported intense pain on peripheral i.v. infusion, so we used first 1,000mL of saline, and then Ringer and Kalium progressively.

Family reported repeated episodes of binge eating at home with ingestion of Coke and high amounts of food, after that unprovoked vomiting. Discussion with patient revealed also depression, this kind of food pattern was the patient's cry for help due to unresolved adolescence trauma, even if she had family and friends support now. We tried also to relieve the pressure from job.

Next day iv saline 500 ml, Ringer 1000 ml, Kabiven were introduced, with almost complete correction of hypokaliemia.As patient had urinary tract infection we added Gentamycin 320 mg/day and Ciprofloxacin 400 mg/day, for seven days, with good evolution.

Third day we introduced Fresubin – enteral formula – 500 ml/day, divided in 7-8 meals, no more than 100 ml/meal, associated with Osetron and Controloc on i.v. line. Patient stopped vomiting the third day and the next day we introduced small amounts of baby food – milk and egg, fruits puree, small amounts of soup with chopped meat.

By seventh day patient gained enough weight so we tried to reduce the amount of Fresubin and Kabiven and leave her on oral intake of mashed food, but this induced reappearance of vomiting. X-ray revealed no passage of barium due to complete gastric stenosis, so i.v. nutrition was resumed.

Laboratory 8 a.m. serum cortisol was more than 10 mcg/dl, so we excluded Addison disease.Patient had low TSH and low T3 levels – confirming sick euthyroid syndrome and hypotalamic amenorhhea with low Estradiol levels – 17 pg/ml.

In the last 3 days we introduced small amounts of rapid insulin – 10 U/day to improve anabolism.Patient reached 47 kg, with mild edema in the legs and was discharged in the 12th day of admittance.She still has mild hypoproteinemimia – albumin 3.2 mg/dl, total proteins 5,6 g/dl and mild hypocalcemia – 8.8 mg/dl.She was discharged with proton pump blocker and prokinetic treatment, associated with buvable ferrum sulfate.

She repeated the endoscopy and was converted to gastric by-pass after 3 days without more complications.

Fever and abdominal tumoral masses

Augustin C. Dima[1], Teodor Artenie[1], Daniel Florea[1], Florina Bold[1], Paul I. Oprea[1]

Abstract: *49 year-old man presented to our clinic for pain in the right hypochondrium, diarrhea, and fever. The clinical examination highlights a tumoral formation in the right side of the abdomen, with firm consistency, poorly defined margins, and present mobility in the deep structures. On biological exams, leukocytosis with neutrophilia, inflammatory syndrome, and hypoalbuminaemia were identified. The first computed tomography exam described parietal thickening of the ascending colon, with infiltrative aspect, and multiple local adenopathies, lomboaortic and interaortocave. Moreover, four nodular liver tumors, with hypodense image in native examination, were identified. The lab tests for infectious diseases were all inconclusives: three hemocultures, three stool samples, and three coproparasitological exams were all negatives.*

Interdisciplinary examinations, internal medicine and infectious diseases, sustained the diagnosis of colonic neoplasm with peritumoral abscess and liver pseudo-tumoral masses. The colonoscopy did not revealed any bowel lesions relevant for neoplasia. This result as well as the bio-clinical context imposed abstention from surgical intervention.

Wide spectrum antibiotics and symptomatic treatment were initiated. But, ten days after hospitalization, the second computed tomography exam showed reduction of the ascending colon wall thickness associated with significant increases of the liver tumors is so revealed. The investigations for other possible etiologies were so continued.

Keywords: *colon tumor, intestinal amoebiasis, liver abscesses.*

INTRODUCTION

In current clinical approach of abdominal pathology one must not forgot the rare disorders whose clinical picture and imaging could mime neoplasia, pathology so frequent today.

The current diagnosis of colon tumors is made especially using imaging diagnostic methods, whose accuracy is high, facilitating anaccurate stage diagnosis, very important in determining therapeutic tactics. But it must not be forgotten also the importance of classical clinical features that could bring essential elements for the certainty diagnosis.

CASE REPORT

We present the case of a 50-years old patient, smoker, diabetic, hypertensive, who presented for right upper hypochondrium pain, diarrhea, nausea, febrile syndrome, with the onset of symptoms about 48 hours prior to presentation.

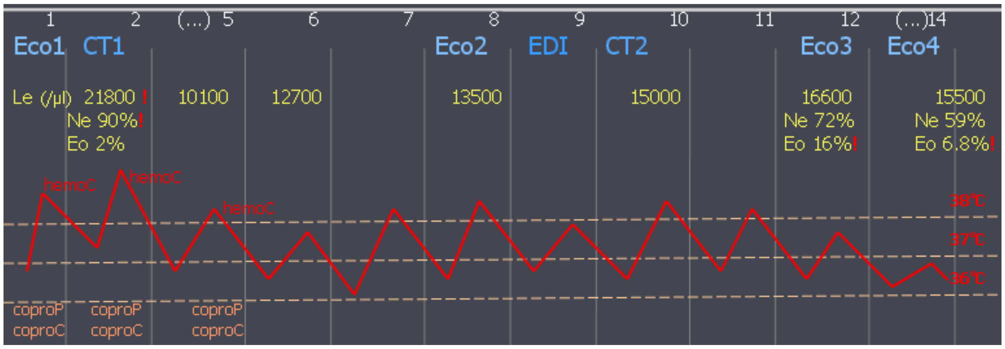
Clinical examination revealed hypochondrium and right flank sensitive abdomen, tumor mass in the right flank, with firm consistency, imprecisely defined, relatively mobile on the deep plans, without signs of peritoneal irritation, fever (38.7˚C), shivering.

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

Biologically, neutrophilic leukocytosis, inflammatory syndrome, and hypoalbuminemia were noted. Plain chest and abdominal radiography were without pathological changes (Figure 1). Abdominal ultrasound identified hypoechogenic liver formations.

Figure 1: Biological evolution during diagnostic and after specific treatment



CT exam identifies hepatomegaly and four nodular liver formations: hypodense on native examination, irregularly shaped, with uneven structure, apparently separated from their dense walls (Figures2a, 3a, 4a). In addition, a parietal tumoral formation belonging to ascending colon, located toward liver angle, showing asymmetrical narrowing partially iodophile (with a maximum thickness of 2.1cm), infiltrating the cecum – ascendant digestive wall and the adjacent fatty abdominal tissue that adheres to the liver capsule. Perilesional, lumbar aortic and interaortocaval adenopathies, (with maximum dimensions of 1.3cm) (Figures5a, 6a, 7a) were also described.

Figure 2(a, b): Computer tomography exam: first two liver masses evolution under treatment

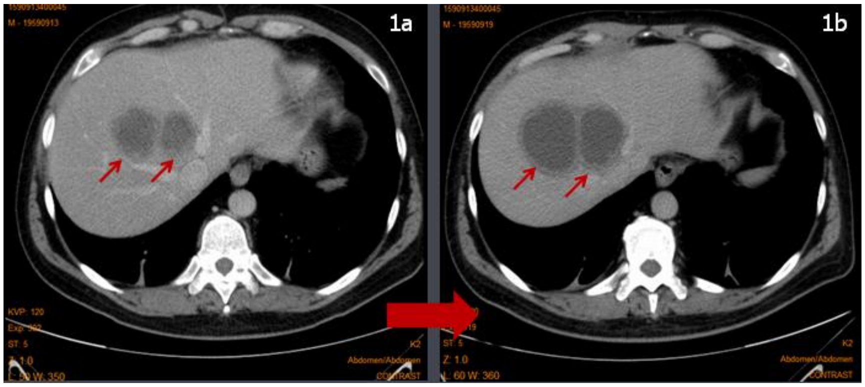


Figure 3(a, b): Computer tomography exam: liver masses evolution under treatment

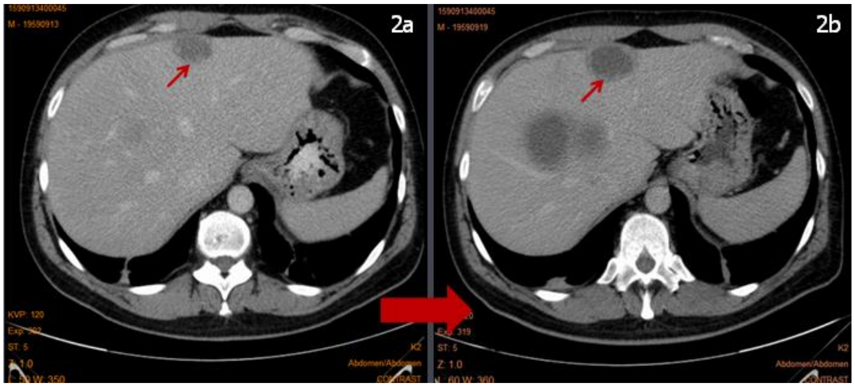

Figure 4(a, b): Computer tomography exam: liver masses evolution under treatment of the third tumoral mass

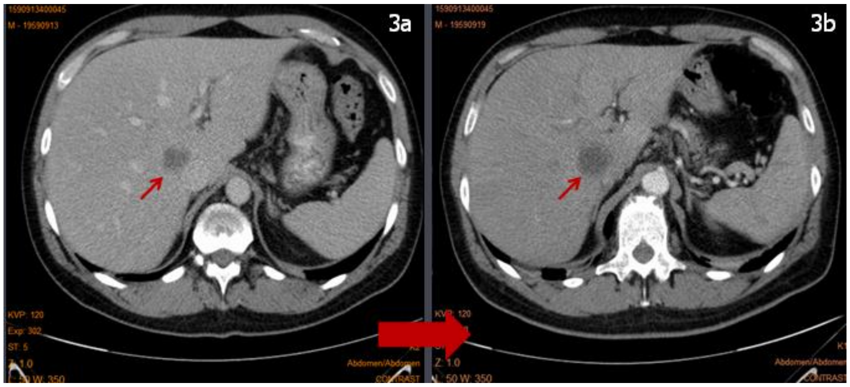

Figure 5(a, b): Computer tomography exam: colon tumor evolution under treatment

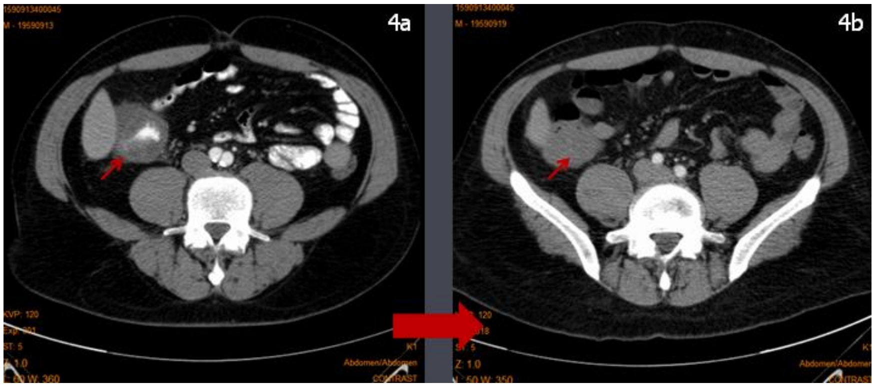

Figure 6(a, b): Computer tomography exam: colon tumor and local adenopathies evolution under treatment

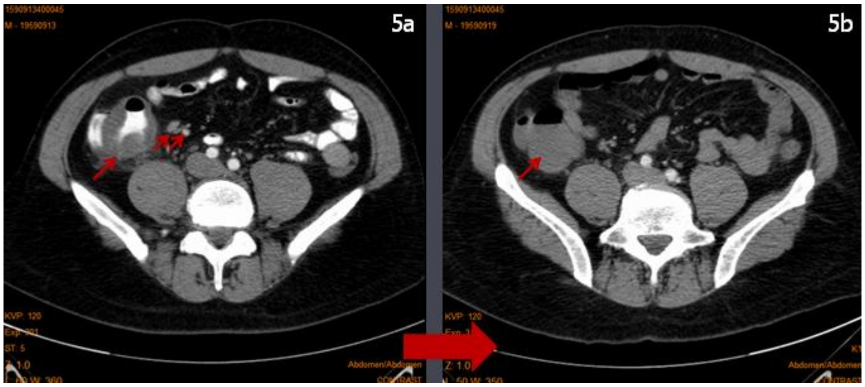

Figure 7(a, b): Computer tomography exam: colon tumor evolution

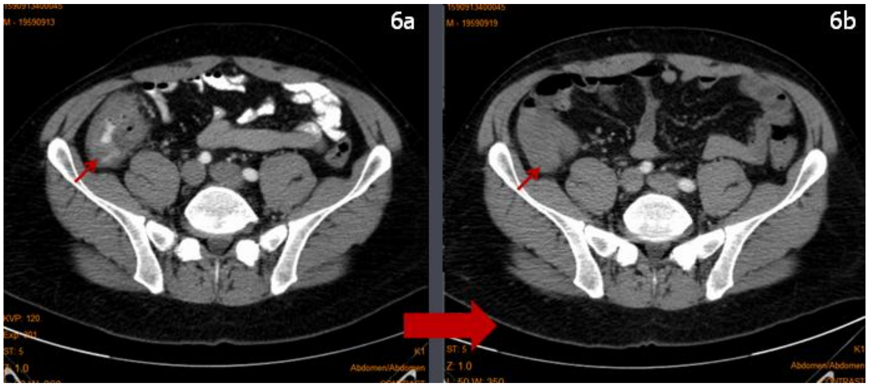

The paraclinical picture was completed with three negative blood cultures, three negative copro-parasitological exams, three negative coprocultures and tumor markers (carcinoembryonic antigen, CA 19-9, alpha-fetal protein) negative (Figure 1).

Internal medicine and infectious diseases examinations declines the eventuality of infectious or parasitic primary etiology of colony formation and supports the diagnosis of colon cancer with peritumoral abscess and septic liver determinations.

At this point, the imaging seems to support thediagnosis of ascending colon tumoral mass associated with secondary liver metastases or with local associated infection and liver abscesses.

Clinical arguments, however, given the relatively sudden symptoms onset, are pleading for diverticulitis or segmental colitis of the ascending colon with septic determinations in liver. Therefore, we consider it appropriate to postpone surgery and to make further investigations.

It was initiated treatment with broad antibiotic spectrum (imipenem – cilastatin 500 mg/ 500 mg, 4 times daily, linezolid 600 mg 2 times daily, both for 10 days and Moxifloxacin 400 mg daily for 5 days) associated with symptomatic treatment.

Lower digestive endoscopy describes in the rectum, at 4-5 cm from the anus, a 1 mm polyp covered by normal mucosa, at 10 cm from the anus a 2 mm sessile polyp, covered with congestive mucosal, biopsy was performed. In the sigmoid colon, to about 25 cm, a 10 mm semi pedunculated polyp, cylindrical, covered by the congestive mucosa, supple for biopsy. At the descending colon polyp plan, ovoid of 7-8 mm, covered with inflamed mucosa, supple for biopsy. Transverse and ascending colon without changes.

Caecum, opening of appendix and the ileocecal valve without modifications.

The morphopathologic diagnosis of colon polyps was of tubular adenoma. So, the endoscopic examination does not argue for tumor etiology.

The evolution under treatment was favorable: reducing the number of daily diarrheal stool (from 10 to 12 per day to 2-3 per day) and also fever – under vesperal fever and the overall condition has improved. Biologically, continuing with leukocytosis with neutrophilic, but at lower values and the increasing of cholestasis defining liver enzymes (Figure 1).

We repeat, on day 10 – from the admission – the CT examination and we see a significant increase in volume of liver formations, the largest with a diameter of about 7cm, with better separation than previously, clear evidence of the relatively thick walls and of clear fluid content (Figures2b, 3b, 4b). Also, the marked reduction in the ascending colon thickness and reduction in the size of abdominal adenopathy (Figures5b, 6b, 7b) were noted.

Diagnosis of infectious disease is gaining before a possible neoplastic etiology, se we ask forparasitology and infectious diseases check-up and serological determinations.

Positive diagnosis is supported by the presence of Ig G type anti-Entamoeba histolytica antibody (negative Entamoeba histolytica antigen, negative Echinococcus antibodies, negative Giardia duodenalis CoproAg and Cryprosporidium CoproAg) for which specific treatment is initiated.

Thus, the positive diagnosis was: liver amoeba disseminated abscesses in both lobes, in remission and intestinal amoebiasis affecting the ascending colon, submitted.

The patient’s evolution after the initiation of the etiological treatment was favorable with improvement of the general condition, normalization of blood counts at two weeks of antiparasitic ambulatory treatment and marked reduction of liverabscesses dimension with their disappearance in a year.

DISCUSSIONS

Entamoeba histolytica is a protozoan that is an important health problem in tropical and subtropical countries [1]. Infection is fecal-oral, 90% of those affected remain asymptomatic, being determined by ingestion of food contaminated with parasite cysts [2]. It affects particularly the gastrointestinal tract (more frequently the check and ascending colon) and liver [3].

The difficulty of diagnosis in this case was given by the initial CT imaging appearance of ascending colon tumor, accompanied by the negative coprocultures and coproparasitological exams.

Imaging appearance of colonic amoebiasis mimicking neoplastic pathology has been described in the literature, but this presentation as a colon tumor formation remains a rare occurrence[4][5]. Most frequently, the colonic amebiasis diagnosis is done by highlighting the parasite in the stool, the examination of three successive stools leading to a positive diagnosis in 70% of patients [6].

The correct diagnosis in the presented case was obtained only after achieving immunological determinations, serology for Entamoeba histolytica is positive in up to 90% of patients with amoebic colitis [7].

Also, another feature that hindered the diagnosis was the initial presence of neutrophilic leukocytosis, with no eosinophilia (Figure 1), which could be explained by possible plurimicrobial superinfection of the parasite gateway from ascending colon.

After starting antiparasitic treatment an increase in eosinophils in serum is observed, most likely secondary to parasitic destruction and thus the emergence of new antigenic elements.

Important in the proper management of this patient was refraining from any surgery and introduction of specific therapy (Metronidazol) despite the pressure brought by imaging and biological data. Surgery in Entamoeba histolytica infection is a must in cases of acute colitis with necrosis and perforation when it may be necessary even total colectomy [8][9] and could also be followed by many complications.

Another problem of therapeutic tactic was the discussion on the need for drainage of liver abscesses, their sizes being significant. The ultrasound tracking has shown that the effective antiparasitic treatment was enough, observing the gradual decrease of their sizes, with their disappearance one year after the initiation of antiparasitic treatment.

In general, the literature does not support the need of drainage for uncomplicated liver amoebian abscesses [10]. Could be drained big liver abscesses (>300 cm^3) or when there are questions about the etiology of liver abscess, like in the case of pyogenic liver abscess [11][12] when cultures from drainage samples could be informative on the etiology and further treatment.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented athttp://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of theirmanuscript: *Introduction, Methods, Results, DiscussionAcknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.

2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research

must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted 'in press' manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

EDITORIAL

About clinical medicine: Is there still such a thing?

Dan Mischianu

Gral (R) Prof DAN MISCHIANU
Chief of Urology Clinic, Carol Davila Central Emergency Military Hospital
Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

The other day, a distinguished and well known specialist radiologist from Bucharest shared with me two absolutely surprising things.

First: not long ago, an experienced internal medicine physician addressed expressly with the request to radiologicaly examines a patient with, in his opinion "acute pulmonary edema"! The radiologist told me that the “acute pulmonary edema” was actually a "spontaneous pneumothorax" probably due to rupture of emphysematous bubbles. The thoracic surgeon solved the so-called "acute pulmonary edema" actually "spontaneous pneumothorax" by specific means...

The second issue told by the radiologist: I can sit at home in front of my laptop and receive scanned images of patients from different locations (clinics, private hospitals) in the country (Bacau, Constanta, Baia Mare and so on), then I say my opinion and the fee is in my account!

I asked him slightly amazed: Yeah, well, but do you not feel the need to learn more about that patient? Did you forget what we learned in medical and surgical semiology that 80% of the diagnosis belongs to anamnesis? Do you not need to palpate, to auscultate or to listen to what the patient tells you...? Have you not learned anything from the mistake of the internist who "din not use a stethoscope" to find, in fact, that he had no vesicular murmur? My friend did not answer…

In fact what do I want to say in this editorial?

First I want to say that our guild lives in a perfect confusion: notions or concepts of "evidence-based medicine (EBM)", "alternative medicine", "noninvasive" medicine, "medicine x, y, z" and many others can only leave room for speculation. Medicine, as illustrated, has always been great at removing great speculations because of phantasmagoric individuals like Paracelsus or Mesmer...

Secondly, in Adevarul newspaper from 02/19/2016, Theodora Şopaltă, a journalist, was writing sententiously: "There are five types of doctors. Which one do you prefer?" The first type, in the opinion of the author is “The clever" (30% of respondents voted for him), then comes "The Digital doctor” (which probably specify diagnosis texting his phone! preferred by 8% of respondents), then comes “The Wise man" who do not talk to patients about their illness but gives them an accurate diagnosis. Go figure it! In fourth position lies "The Idealist", preferred by 24% of patients, said to be a younger version of "intelligence" and the ending is marked by "Only You", a "pragmatic option of alternative medicine."

Thirdly, I say that doctors may be labeled as "made and born" to practice this noble profession, for which are made after the Hippocratic precepts and not by strange and awkward ideas, good and honest doctors with knowledge of human nature, easily grasping which in this profession gives you a disadvantage and "good for nothing doctors" who easily realize that there is no place for them amongst us and change their job to managers, adventurers, free – thinkers and so on.

To end this Editorial I conclude by saying that a good and honest clinician is the one that accepts and applies the perennial teachings of Hippocrates of Cos and takes into account the lessons of the Great surgeon and Great clinician, Professor Dr. Ion Juvara:

"Whatever novelty and complexity of laboratory methods of investigation, clinical retains its entire value, observation of man by man offering truths that never grow old”

I believe and hope that there still is the so-called "Clinical medicine"!

MRI fusion biopsy vs transrectal ultrasound guided biopsy – A literature review

Constantin A. Rădulescu[1], Mihai F. Rădulescu[2], Gina A. Ciucă[1], Dan Mischianu[1,3]

Abstract: *Introduction: Current diagnosis of prostate cancer is based on transrectal ultrasound guided random biopsies. These procedures alongside with the discovery of PSA lead to a tremendous improvement of prostate cancer diagnosis rate in the last decades. Random ultrasound guided biopsy has its minuses and several attempts were made to improve the detection rate of the disease. MRI-US fusion targeted biopsies is one of them.*
Aim: This paper is a literature review of several important European studies and tries to draw a conclusion for the usefulness of MRI-US image fusion prostate biopsy in improving prostate cancer detection
Material and methods: We have analyzed 5 papers published since 2013 which compare random ultrasound biopsies with MRI-US fusion. The analyzed parameters were clinical significant cancer detected as described by the study and any cancer detected
Results: All 5 papers show superiority in cancer detection rates for both clinically significant and any cancer.
Conclusions: MRI-US is a useful tool for improving detection rate of clinically significant prostate cancer.

INTRODUCTION

Prostate cancer is a serious public health matter, being the first cancer in men in terms of incidence and the second cause of cancer death in the U.S. Cancer, in general is taught to surpass in the following year cardiovascular diseases as the leading cause of mortality. Prostate cancer, in particular is becoming more and more important due population aging. [1]

While throughout the history prostate cancer was poorly understood, with few cases recorded due to the low life expectancy, during the XXth century groundbreaking discoveries were made in understanding, diagnosing and treating the disease.

Early diagnosis methods included open transperineal biopsies, blind transperineal needle biopsy and finger guided transrectal biopsy. First attempts to use transrectal ultrasound for prostate imaging were made by Takahasi and Ouchi in 1963 but they obtained poor images [2]. Watanabe in 1968 performed first clinical useful TRUS. In 1989 Hodge and al. started the modern era of standard sextant

[3] Carol Davila University of Medicine and Pharmacy, Bucharest

transrectal ultrasound guided needle biopsy. Stamey developed a technique which consisted in performing a biopsy without knowing the tumor location within the prostate. Stamey's method was a major advance over older methods in which biopsy needles were guided only by the examining finger.(2) During the late 1990's and early 2000's standard protocol was modified introducing extended and saturation biopsies. Nowadays it is estimated that several million biopsies are performed each year around the globe.

Ultrasound guided transrectal biopsies have 2 major disadvantages: detection of focal carcinomas with little or no clinical significance on one side and the important percentage of falsely negative biopsy cores.

MRI was invented in 1971 by Paul C. Lauterbur for which he was granted Nobel Prize for Medicine in 2003. MRI evolved as being the most important tool for prostate cancer staging, especially if performed in a multiparametric manner.

Prostate biopsies can be performed directly under IRM guidance or images may fused either in a cognitive manner, a method dependent on operator's experience, or MRI-US image fusion may be used. When using US-MRI fusion, standard transrectal ultrasound is performed and software is utilized to fuse the ultrasound images, at the time of the examination, with IRM images that were obtained before.

3D images of the prostate are obtained [3]. Fusion devices use a variety of technologies to perform image fusion. There are devices which perform robotic tracking via a mechanical arm with built-in encoders with commercial products: Artemis and BioJet. Electromagnetic tracking is used by the following UroNav and Hi-RVS. A 3D US probe is used for tracking and fusing images by Urostation. [4]

MATERIALS AND METHODS

We have analyzed 5 major studies which were performed since 2012 in terms of number of subjects, medium PSA level, overall cancer detection and clinically significant cancer detection rates. All 5 studies analyzed were paired cohort studies which compared transrectal standard biopsy with MRI-US fusion biopsy. The population analyzed was heterogenous. The only thing that was common to all patients was high PSA levels. One study, (Sonn GA et al, 2014)[5] had only patients with prior negative biopsy while the other 4 studies had mixed patients with or without prior negative biopsies. The percentage between patient with and without negative biopsies varied.

The number of patients varied between 30 (Fiard et al, 2013) [6] and 347 (Kuru et al, 2013) [7] with a total of 677 patients. Medium PSA recorded in each study varied between 6.3 ng/ml (Fiard et al, 2013) and 9.85 ng/ml (Kuru et al, 2013).

Clinically significant prostate cancer was defined by each study. Sonn et al defined clinical significance as Cancer positive cores with length 4 mm or more or Gleason 3+4.

Kuru et al used the NCCN (National Comprehensive Cancer Network) criteria. Fiard et al and Rud[9] et al considered clinical significance when Gleason 7 (3+4) or higher was recorded on biopsy cores while Rastinehad et al[8] used Epstein criteria for clinical insignificant tumors: clinical stage < T1c; PSA density < 0.15 ng/ml; fewer than 3 positive cores and less than 50% cancer on positive cores.

Clinically significant disease, defined as above, was diagnosed by means of transrectal ultrasound guided biopsy in 4.8% (Rud et al,2012) to 38% cases (Kuru et al, 2013) with a mean value of 25.26% and by means of MRI-US fusion biopsy in 21.7% (Son et al, 2014) to 50% cases (Rud et al, 2012) with a mean value of 40,76%.

The difference in diagnosing clinically significant disease varied between 7% to 41.4%. MRI-US fusion biopsy was more accurate in diagnosing clinically significant prostate cancer compared to US transrectal biopsy with an overall advance of 17.36%.

When analyzing all types of cancer both clinically significant and insignificant 4 out 5 studies showed superiority of MRI-US fusion biopsy ranging from 0.2% to 53.2%. Sonn GA et al reported 27.5% for

TRUS biopsy vs 23.7 % for MRI-US fusion. This difference in favor of TRUS is probably linked to the study design as it is the only cited study that enrolled only patients that had undergone a prior negative TRUS biopsy.

Table1: Prostate cancer both clinically significant and any cancer

Paper	Clinically significant TRUS	Clinically significant MRI-US fusion	Any cancer TRUS	Any cancer MRI-US fusion
Sonn GA et al	14,7%	21,7%	27,5%	23,7%
Kuru et al	41,1%	50,4%	50,4%	50,6%
Fiard et al	33,3%	50%	43%	55%
Rastinehad et al	32,4%	44,8%	48,6%	50,5%
Rud et al	4,8%	46,2%	14,3%	67,5%
Medium values	25,26%	42,62%	36,76%	49,46%

DISCUSSIONS

All studies show superiority for detecting clinically significant disease with a smaller number of biopsy cores for MRI-US fusion biopsy and all but one showed overall superiority in detection of prostate cancer.

The disadvantages of this review are the fact that there isn’t a standardized definition of clinical significance, the lack of homogeneity of the analyzed population, the fact that some studies have enrolled both patients with prior biopsies and patients without biopsies, and the lack of standardized protocol for MRI-US fusion biopsy as there is a standard protocol for TRUS biopsy.

CONCLUSIONS

MRI-US fusion biopsy has proven to be more accurate in detecting clinically significant cancers but is still long way from becoming a standard procedure because of the complex technique required, the financial burden caused by the need of a prior MRI.

MRI is capable of accurately diagnosing prostate cancer, in assessing its extension, its aggressiveness. MRI is also a useful tool for following patients with prior diagnosis of prostate cancer and probably, in the future it will be the major tool for focal therapy of the tumor.

Transrectal ultrasonography still holds the crown for prostate cancer detection and will certainly remain the most used guidance technique for prostatic biopsies for long time with good results in the general population. Patients with negative biopsies and who experience a continuing rise in PSA levels, patients at risk when talking of hereditary antecedents of prostate cancer and some other risk categories may and will certainly benefit from the development of the MRI fusion technique.

The role of contrast-enhanced ultrasound in risk assessment of carotid atheroma

Silviu Stanciu[1], Cristina Enciu[1], Ioana Răduţă[1], Dan Stoicescu[1], Adrian Anghel[1], Daniela Anghel[1], B. Olan[1], Lucian Ciobîcă[1]

Abstract: *Background and objective: Contrast-enhanced ultrasound, used to assess atherosclerotic carotid plaques, improves visualization of vessel wall irregularities and depicts intraplaque neovascularization. This article illustrates the use of contrast-enhanced ultrasound in the risk assessment of carotid atherosclerotic lesions, especially in challenging plaques evaluation.*

Materials and methods: For 23 patients with difficult duplex ultrasound examination due to carotid tortuosity or calcifications we assessed plaque morphology (contour, echogenicity and stenosis degree) using contrast substance (Sonovue, Braco) with dedicated vascular low mechanical index CPC software.

Conclusion: Contrast-enhanced ultrasound is a new, noninvasive, and safe procedure for imaging carotid atherosclerotic lesions. It is a valuable tool for evaluating the vulnerable plaque at risk for rupture and for the diagnostic of the development and severity of systemic atherosclerotic disease.

INTRODUCTION

Carotid atheromatous pathology is responsible for almost 1/3 of strokes through 3 basic mechanisms: atherothrombosis, distal embolism from plaque origin and hemodynamic effect in the case of significant, severe stenosis (1).

Carotid ultrasound technique remains the benchmark for the assessment of carotid-vertebral arterial axis, mainly regarding the presence of obstructive atherosclerotic plaques with a proper evaluation of morphology and stenosis degree, by combining the two methods of examination: Duplex mode-B mode and Doppler mode (Color and Spectral).

Numerous studies have shown the beneficial role of endarterectomy or stenting in stroke rate reduction, in symptomatic and asymptomatic patients with significant stenosis of over 70%, but there is no clear attitude regarding the therapeutic approach of asymptomatic patients with a lower degree of stenosis. In these patients, in whom stenosis has no cerebral hemodynamic effect, several studies emphasize on plaque morphology, by identifying unstable plaques which would play an important role in the development of symptoms (2).

Often, we encounter in daily clinical practice cases where carotid axe imaging becomes challenging due to intense calcifications in the carotid bulb and origin, due to the presence of carotid tortuosity or because of the impossibility to distinguish between

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest

preoclusive (over 90%) stenosis and complete occlusion, which would change the therapeutic approach (3,4).

To overcome these limitations and better characterize unstable plaques, by highlighting the intraplaque neoangiogenesis (5), recently a new imaging technique has been developed using contrast substance, which has the advantage of strictly vascular and plaque and wall vascularization distribution.

MATERIALS AND METHODS

During the last year, for 23 patients with difficult duplex ultrasound exams due to carotid tortuosity or calcifications we performed a contrast enhanced evaluation in order to assess plaque vascularization and stenosis degree.

In consequence, the protocol for plaque morphology description (contour, echogenicity and stenosis degree) consists in 1 ml bolus of contrast substance (Sonovue, Braco) administered through a catheter in the right arm, followed by 10 ml bolus of saline with the acquisition of 6 seconds clips during 4-5 minutes, maneuver which can be repeated to achieve the objectives of the study.

In our department we currently use dedicated vascular CPC software with low mechanical index, integrated into a SIEMENS Sequoia 512 CV system.

In each case we observed the contrast substance plaque penetration, carefully identifying and assessing intraplaque vascular pattern.

Detecting intraplaque angiogenesis

In the majority of patients (68%) with echogenic plaques and no significant stenosis (lower than 70%) intraplaque vascularization has been found, with outside to inside filling pattern, data similar to literature findings (see images).

The existence of this new angiogenesis vessels, mainly situated at the base of atheromatosic plaques, can be considered a risk zone for possible plaque rupture, resulting in major stroke.

Figure 1: Transverse cross section right after left CCA bifurcation, 30 seconds after contrast substance has been administered. Note the lack of opacification of left ICA due to the presence of atheromatous plaque responsible for a 60-70% stenosis.

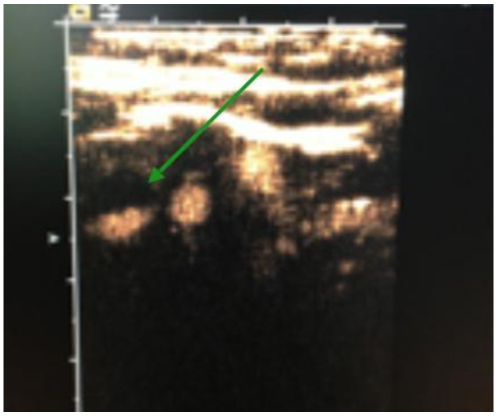

Figure 2: Longitudinal section 40 sec after the injection allowing plaque visualization at the origin of the left internal carotid artery with contrast enhancement at the base (arrow)

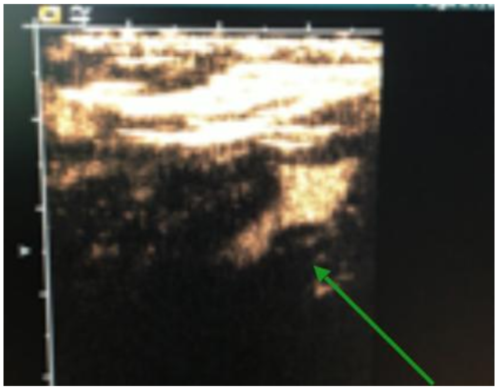

Figure 3: Same plaque from figure 2 at 60 seconds after injection

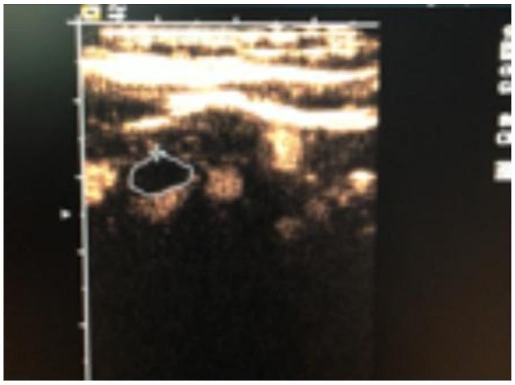

Figure 4: Contrast enhancements at 70 seconds with a filling patter from the outside to inside

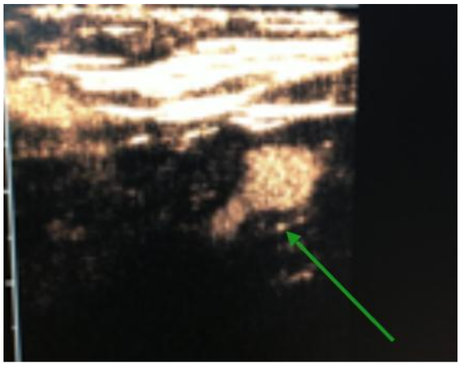

In consequence, identifying intraplaque neovascularization in patients with no significant carotid stenosis can be considered a noteworthy additional argument when considering an interventional procedure (stenting or endarterectomy) for stroke prevention.

DISCUSSION AND CONCLUSIONS

The concept of unstable or vulnerable plaque, similar to that seen in coronary pathology, is based upon identifying dangerous plaques with immediate stroke like complications, with acute inflammation and angiogenesis (which precede and cause plaque rupture or ulceration), that can't always be detected through conventional duplex ultrasound.

Carotid ultrasound remains the leading non-invasive exploration regarding pre-op/pre-interventional or post-op/post interventional functional and anatomic evaluation. Contrast-enhanced ultrasound studies, bring additional information regarding carotid stenosis quantification in difficult evaluation situations (calcified plaques or difficult to explore vascular tortuosity) but especially brings functional information regarding intraplaque vascularization, thus identifying unstable and high stroke risk plaques allowing an appropriate therapeutic approach.

The importance of life quality questionnaire in patients with prostate cancer, pre- and post-radical prostatectomy

Gina A. Ciucă[1,2], Ovidiu Bratu[1,2], Dan Spînu[1,2], Marius Dinu[1], Cătălin Farcaș[1,2], Constantin A. Rădulescu[1], Robert Popescu[1], Dragoș Marcu[1], Dan Mischianu[1,2], Petru Armean[2,3]

Abstract: *This study analyzes the satisfaction of the patients with radical prostatectomy according to the signs and symptoms included in the EORTC QLQ – C30 and EORTC QLQ – PR25 questionnaires, including their relation with the health state that influences the pre and postoperative life quality.*

Fifty patients with prostate cancer in a localized stage were studied and analyzed in a prospective manner and for a period of 12 months, before and 6 months after the radical prostatectomy. In choosing the patients, the common denominator was the use of the same postoperative plan and the lack of postoperative complications, as well as the lack of chronic diseases.

Erectile dysfunction, urine incontinence were quite frequent after radical prostatectomy, while the urinary obstruction and the weak urinary stream were less frequent. In this regard, people noticed a significant decrease of life quality.

Although the study addressed a small group of patients, the results are similar to those belonging to other clinical studies. Even if the aspect of life quality is more rarely taken into account, the questionnaires regarding the life quality are specific, useful and quite cheap in evaluating different therapies.

Keywords: *life quality, prostate cancer, questionnaire*

INTRODUCTION

Prostate cancer represents a disease with increased prevalence, being the second cause of death in U.S.A, on the first place being the lung cancer. However, the prostate cancer shows optimistic survival rates, the rate of the deaths caused by the prostate cancer decreased in the U.S.A, from the beginning of 2007 with 3.2%[4]. This fact led to the appearance of a model of patients with prostate cancer, patients for whom the quality of life is important, as well as the impact of the disease on this.[5].

For those who study the clinical problem, the aim of evaluating life at the patients with prostate cancer consists in evaluating the effects of the treatment on the symptoms and in identifying the negative impact of the disease on the life of the patient.

The quality of life is a concept that has started to be studied and taken into account in 1946 when in the

Preamble of the Constitution of World Health Organization, health was defined as it follows: ,,*Health is the state of complete physical, mental and social wellbeing that does not reduce at the absence of a disease or of an infirmity"[1,2].*

Smith and his contributors consider the notions of life quality and the health as being two defined concepts, the life quality being related even more to the mental health, while the state of health hints at the physical function [3].

Meaning ,,a holistic auto evaluation of satisfactions regarding the individual", the life quality is a much – disputed concept, multidimensional that, though seems quite easy to understand it, is difficult to be defined.

In a more restrictive meaning is used the term of life quality regarding health ,,health related quality of life" (HRQL),to define the influence of health and nursing on the life quality, being influenced by numerous factors like: financial state, habitat, the work place, the spirituality, the social support and the health of the individual [2].

The evaluation of the aspect regarding the quality of life in patients with prostate cancer is done at a large scale in the clinical studies, but it must be underlined the importance of using these evaluation methods in clinical practice [1].

The questionnaire, a descriptive instrument, is the one through which the evaluation is done in a subjective manner a wide range of the disease effects that are, later, resumed into a final score.

The evaluating instruments of the quality of life come to complete the other methods of investigation of the patient with prostate cancer, for this very reason it would be opportune to facilitate the use of these by the people who study clinical problems, the subsequent therapeutic conduct being able to improve the quality of life for these patients.

The most used questionnaires in the clinical practice in evaluating the patients with prostate cancer are the following: EORTC QLQ-PR25 and EORTC C-30 questionnaires.

The quality of life as a medical concept explains the effects of diseases and those of the therapy on the stage of comfort for the patient that is the subject of evaluation with the help of the questionnaires.

The questionnaires can be completed by the medical personnel, the patient being asked the questions after having read and signed the informed consent or directly by the patient.

The first method has the advantage that the doctor can explain the patient the questions more accurately, diminishing the misunderstandings, but the result cannot have a maximum accuracy as not all the patients can be very honest while facing other persons.

MATERIAL AND METHOD

Fifty patients with prostate cancer in a localized stage were studied prospectively for 12 months, before and at 6 months after the radical prostatectomy between January 2015 – December 2015, at the Urology Clinic of the Carol Davila Central Military Hospital.

In choosing the patients, the common denominator was the use of the same postoperative plan and the lack of postoperative complications, as well as the lack of chronic diseases.

The average age of the patients included in study was of 65.

The patients were asked to fill in the EORTC C-30 and EORTC QLQ-PR25 in Romanian language, after having read and signed the informed consent.

The characteristics of the group of patients were recorded and processed in a SPSS database (version 22 – Chicago k, USA).

The EORTEC C – 30 questionnaire has 30 questions that shows us a pre and postoperative image of the patient, regarding the cognitive, emotional, social functions or regarding the signs and symptoms of the patients, using a scale with more items or singular ones.

The questionnaire, excepting the two last items, can be completed with values between 1 and 4, so,(A) the absolute amplitude of the variation of answer is 3. The scale of life quality is given by the answers at the questions 29 and 30 at which the patients can choose values from 1 to 7, the absolute amplitude being of 6.

Items	Number of items	Number of question
Physical state	5	1 - 5
Daily activities	2	6, 7
Emotional states	4	21 - 24
Cognitive functions	2	20, 25
Social and family relations	2	26, 27
Tiredness	3	10, 12, 18
Nausea and Vomiting	2	14, 15
Pains	2	9, 19
Dyspnoea	1	8
Insomnia	1	11
Anorexia	1	13
Constipation	1	16
Diarrhea	1	17
Financial problems	1	28
General health state	1	29
Life Quality	1	30

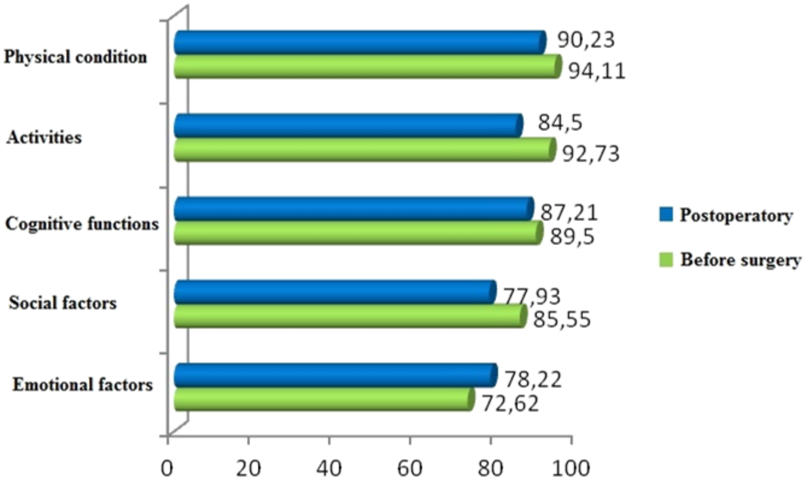
To analyze the questionnaires I used a different formula for functions, namely: Value _functions = 1 – ((Raw score – 1)/Absolute Amplitude)*100 comparing to Value _ symptoms = Raw score -1/Absolute Amplitude)*100.

As a result, I noticed that a higher value of the functions shows a higher rate of functionality and independency, while a higher value of the symptoms shows problems of dependency of the patient.

One can notice in the chart that, only emotionally, the patient feels better after 6 months after surgery. I must mention that the younger patients (<65 years old), consider that, physically and socially speaking, they were better during the preoperative period.

The indicator of the physical state is made up of 5 items: the resistance of hard activities, independency in dressing and eating, as well as the chronicle tiredness and the need of laying in bed. From the questionnaire, one can see that the physical resistance of the patient decreased from 94.11 to 90.23.

Figure 1: Score of life quality regarding functions



One can see an increase of tiredness after prostatectomy, from 11.1 to 16.2 and, also in the symptoms of nausea and vomiting.

The postoperative pain had a significant increase from 10.33 to 12.22.

The tiredness increases proportional with insomnia and the sensation of weakness, and the pain interferes with the daily activities especially at the patients of more than 65 years old.

Figure 2: Score of signs and symptoms

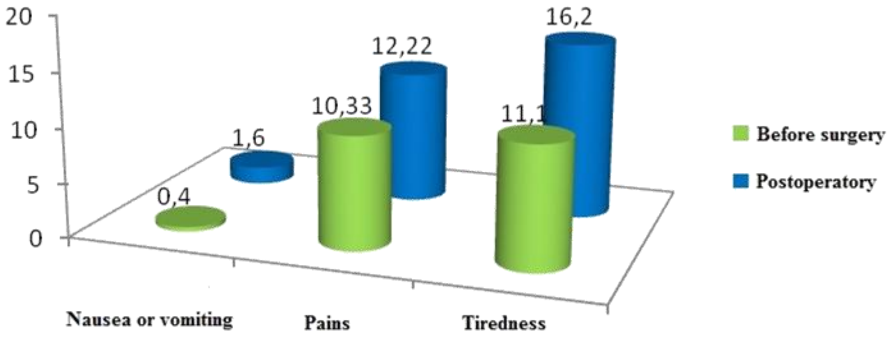


Figure 3: Signs and symptoms

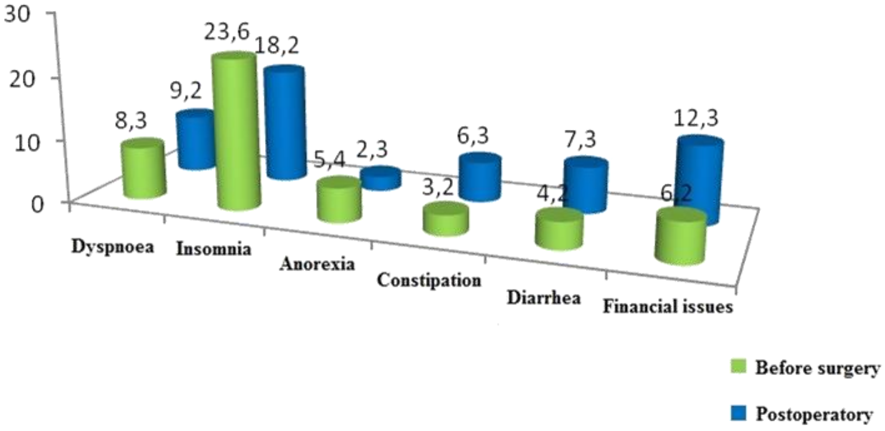

Figure 4: Quality of life

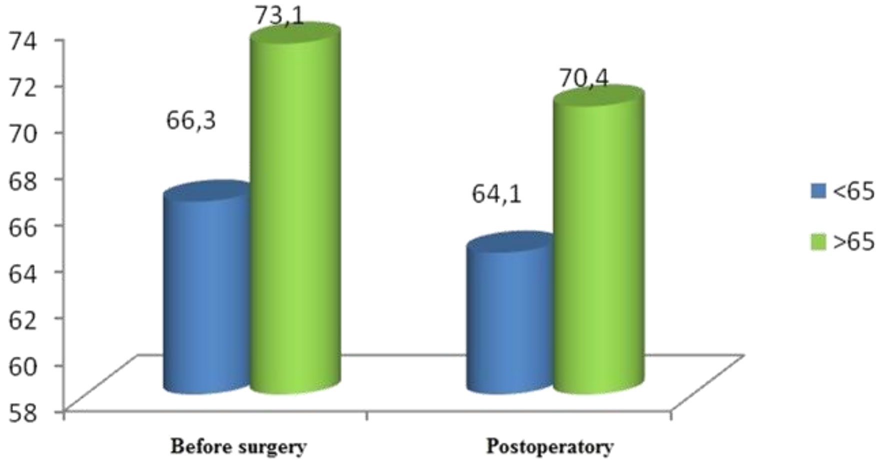

One can see an improvement of the quality of life of the postoperative patient regarding insomnia and anorexia. The digestive symptoms and the financial problems will accentuate postoperatively especially at the patients after 65 years old and the younger ones.

The last items are like a conclusion of the questionnaire permitting the patient to define the last week by the point of view of his health and the manner he sees the quality of his life at a certain time.

Analyzing the data, one can see the most unsatisfied patients on the ground of their physical state and quality of life are the patients younger than 65 years old. Totally, the difference between the quality of life appreciated by people younger than 65 years old pre and postoperative was of 2.2.

Younger patients appreciated the quality of life pre and postoperative lower than the patients of 65 years old.

The EORTC OLO – PR 25 questionnaire contains 25 questions divided into four evaluation functional scales.

Items	Number of items	Number of question
Urinary symptoms scale	9	31-39
Intestinal symptoms scale	4	40-43
Scale regarding the symptoms owing the treatment	6	44-49
Sexual functions scale	6	50-55

The significant differences were regarding the urinary symptoms scale, postoperative 13.86 comparing to preoperative of 7.88. In accordance to the age, there were differences regarding urinary symptoms scale, those of 65 years old had lower scores, at an average of 9.86.

Regarding the sexual functions scale, those younger than 65 had higher scores, at an average of 10.11 units.

The erectile dysfunction appears in a degree of 67% at different levels, while 34.9% shows no affliction of the erectile function.

In the postoperative group 23% presented with mild incontinence while severe and moderate incontinence was present in 4, 7% of the patients.

Postoperatively the frequency of the urinary incontinence was greater in patients older than 65 than those younger than 65.

CONCLUSIONS

To identify the type of treatment is vital for the success of the oncologic therapy of the prostate cancer, though the complications appeared after a radical prostatectomy influences the life quality of the patient. One of the objectives in carrying about patients is in helping at stabilization of the urinary continence and of sexual function, in improving the life quality of the patient. A more critical evaluation of the type of treatment is essential for developing an efficient strategy.

Tumor markers in gastroenterology: useful or useless

Cătălina Diaconu[1], Mădălina Ilie[2], Gaudia Mănescu Avram[1], Laura Voicu[1], Daniel O. Costache[1], Raluca S. Costache[1,2]

INTRODUCTION

Tumor markers are biomarkers that can be found in blood, urine or different body tissues, produced either by cancer cells or normal cells in response to cancer or in different noncancerous conditions (gastrointestinal stromal tumors). Their use varies from cancer screening on a population basis, to staging different tumors or to evaluate the efficiency of the treatment. Most frequently used in gastrointestinal malignancies are: carcinoembryonic antigen (CEA), carbohydrate antigen (CA) 19-9 and α-fetoprotein. However there are many markers that can be useful in dealing with gastrointestinal cancer such as: carbohydrate antigen 125, cyfra 21-1, chromogranin, tumor M2-PK, neuron-specific enolase, smooth muscle actin [1]. Future research show the utility of multiple tumor marker test, when by combining more tests in parallel the predictive value might be increased. For example: when talking about pancreatic or stomach cancer one might combine: CEA, CA19-9 and CA 72-4 [1,2].

ALPHA FETOPROTEIN

So far, alpha fetoprotein is the most studied serological marker in the surveillance of hepatocellular carcinoma, derived from the liver cells and yolk sac [3]. Its' use is debatable. Some studies show that a cut-off of 20 ng/mL carries a sensitivity of 41% to 65% and specificity between 80% and 94%, with a positive and negative predictive value of 25 and 98 percent. Even though The American Association for the Study of Liver Disease (AASLD) guidelines shows that cirrhosis is a possible cause of elevated AFP, its sensitivity (60%) is higher than that of ultrasound (58%). Therefore current data from the literature support the use of AFP combined with ultrasound as the surveillance tests of choice, taken every 6 months, leading to early detection of hepatocellular carcinoma (HCC) [4]. Despite the fact that more than 40% of the patients with HCC have normal AFP, serum levels higher than 500 mcg/L in a high-risk patient is diagnostic of HCC [3,5].

There is a demonstrated correlation between the tumor size and serologic AFP: higher levels with a sudden acceleration appear with HCC that measure more than 3 cm [6]. Moreover serum levels from 1,000 to 10,000 mcg/L are encountered in tumors past 5 cm in diameter. Date from the literature associate high levels of AFP with poorly-differentiated tumors, but further studies are required [7].

False positive values of AFP may be related to flares of activity in chronic viral hepatitis (B or C). Therefore the use of this serologic marker is very important in patients with hepatitis B or C during treatment with nucleotide analogues for hepatitis B or drug acting agents (interferon free) for hepatitis C, when we cannot encounter flares of transaminases [9].

---

[2] Carol Davila University of Medicine and Pharmacy, Bucharest

AFP remains an important prognostic marker in patients after resection or in those who are taken into consideration for transplant. High values over 1,000 mcg/L (believed a surrogate of vascular invasion) associates extremely high risks of recurrent disease after transplantation. Moreover some studies assign this value as an exclusion criterion for liver transplantation in patients with HCC that meet the Milan criteria, in order to improve posttransplant outcome [10]. An assay of serum AFT post-transplant is in order every 3 months for 2 years if initially elevated, then every 6 months. This serologic marker remains an independent prognostic predictor of outcome after ortotopic liver transplant for HCC [11].

Table 1: Causes of elevated serum alpha-fetoprotein [8]

Causes of elevated serum AFP

- Hepatocellular carcinoma
- Cirhossis due to hepatitits B/C
- Non-seminomatous germline tumours
- Ataxia-teleangiectasia
- Pregnancy with babies that carry neural tube defects or Down syndrome
- Other gastrointestinal tumours (gastric cancer, biliary tract cancer, pancreatic cancer)

CARCINOEMBRYONIC ANTIGEN

Discovered in 1965, CEA is a glycoprotein associated with colorectal cancer with a rather low sensitivity and specificity. Even though CEA is not used as a diagnostic test, levels over 5.0 ng/mL can predict a unfavorable prognosis, regardless the tumor stage [12].

A Cochrane review showed that a cut-off value of 2.5mcg/L for CEA carries a pooled sensitivity of 82 percent and specificity of 80 percent. For a cut-off of 10 mcg/L the sensitivity lowered to 68%, but the specificity reached 97 percent, due to fewer false positive values. CEA testing should be done once every 3 to 6 months. One must bear in mind the possible false positive values of CEA (most encountered between 5 and 10 ng/mL). One possible cause is due to the adjuvant therapy with fluorouracyl (therefore some recommend the end of adjuvant treatment before measuring CEA).

There are many arguments against using CEA as a screening test such as: almost half of the recurrences of CRC present normal values of CEA; is has no impact on improving survival and the quality of life and it is not cost-effective. One strong argument in favor of testing CEA is the detection of recurrences [13].

Even though CEA is prohibited in the mass screening and diagnostic pathway of colorectal carcinoma (CRC), it has value in the follow-up of patients with diagnosed CRS according to the American Society of Clinical Oncology guidelines: from surgical treatment planning to post-treatment follow-up and prognosis [14,15]. High serum levels of CEA after 4 weeks of the surgery (this being twice the plasma half-life of CEA) indicate the persistence of the disease, occult metastasis and the need to reevaluate the prognosis

[8]. In conclusion, CEA levels can be associated to the TNM classification of CRC, due not only to its prognostic value, but also the decision of adjuvant chemotherapy.

Table 2: Benign and malignant causes of high levels of seric CEA[8,13]

BENIGN	MALIGNANT
Gastritis	Colorectal cancer
Peptic ulcer disease	Breast cancer
Diverticulitis	Lung cancer
Pancreatitis	Gastric cancer
Liver disease	Pancreatic cancer
Chronic obstructive pulmonary disease	Cholangiocarcinoma
Diabetes	
Cigarette smokers	

Studies showed that high CEA even in node negative patients show a worse prognosis, a higher rate of recurrence, therefore adjuvant chemotherapy could be considered [16].

CEA can be used to monitor the response to treatment in metastatic disease. Whilst the decrease of seric levels of CEA shows the favorable response to the treatment, the rising level of CEA is incompatible with tumor regression [8].

Some studies show that bile CEA levels are elevated in cholangiocarcinoma, but not in benign diseases. Used as a single tumor marker, CEA is neither sensitive enough, nor specific enough to diagnose cholangiocarcinoma [8]. Different combinations of CEA and CA 19-9 are used to diagnose cholangiocarcinoma in patients with primary sclerosing cholangitis.

When using cut-off values of 5.2ng/mL for CEA and 180 U/mL for CA 19-9 the sensitivity was 100% and the specificity reached 78%. Despite this, other data from the literature show a sensitivity of 63% for detecting cholangiocarcinoma in patients with PSC, whilst the specificity when using a combined CA 19-9 and CEA only reaches 33%, albeit with higher specificity [13,17].

CARBOHYDRATE ANTIGEN 19-9

Most frequently used serological marker for cholangiocarcinoma, CA 19-9 has a wide variation in sensitivity and specificity. However, values over 1000 IU/mL are encountered in advanced disease with peritoneal dissemination [18].

CA 19-9 levels can be elevated in 45% of patients with non-malignant affliction since the tumor marker is produced by abnormal cyst epithelium. Benign diseases that can be associated with high values of CA 19-9 are: cholestasis, cirrhosis and cholestatic diseases [18,19].

In patients with primary biliary cholangitis CA 19-9 levels can be increased due to cholangitis or biliary obstruction. Literature states that a cut-off value of 100 IU has a 86% sensitivity and a 89% specificity for cholangiocarcinoma [4]. However CA 19-9 remains the most commonly used serological marker in cholangiocarcinoma with a sensitivity of 89% and a specificity of 86% for a cut-off over 100 IU/mL.

Moreover values over 1,000 IU/mL are associated with unresecability [17].

CA 19-9 has a higher specificity in the diagnosis of cholangiocarcinoma in patients with PBS. Therefore CA 19-9 combined with ultrasound or magnetic resonance cholangiopancreatography (MRCP) are recommended in the annual screening of PBS patients for cholangiocarcinoma [17,20].

Studies shows that the median preoperative CA 19-9 levels in pancreatic adenocarcinoma were 379 IU/mL in patients who would not benefit a curative resection, whilst in patients where it was resected it was 130 IU/mL.

Moreover, values over 130 U/mL postoperative demonstrate unresectability, the likelihood of R0 resection and long-term outcomes [4]. CA 19-9 has a low specificity; therefore studies show that it should not be used as a screening test for pancreatic cancer. However serial testing once every one to three months of this tumor serological marker in the follow-up of patients after curative surgery or in patients with advanced disease that receive chemotherapy was proven useful. Moreover, elevated values of CA 19-9 could precede the radiological images of recurrent disease (must be confirmed with imaging studies or biopsy) [21].

Table 3: Malignant causes of high values of CA 19-9 [18]

- Hepatocellular carcinoma
- Biliary cancer (gallbladder, cholangiocarcinoma, Vater ampullary cancer)
- Pancreatic exocrine or neuro-endocrine cancers
- Gastric, ovarian or colorectal cancer (less frequent)
- Lung, breast,uterine (rare)

Table 4: Cut-off values for CA 19-9 related to the presence of cholangitis (may associate fever, right upper quadrant pain and leukocytosis) or cholestasis (serum bilirubin larger than 3mg/dL) [18]

cut-off ≥ 37 IU/mL

- NO cholestasis
- NO cholangitis

cut-off ≥ 300 IU/mL

- cholestasis
- cholangitis

In patients that underwent curative surgery, the normalization of the values of CA 19-9 within 6 months is associated with twice the mean of survival than in patients that kept elevated CA 19-9 [17].

In individuals with negative Lewis phenotype (7% of the population), CA19-9 is unreliable since the tumor marker needs the expression of Lewis blood group antigen, leading to a false negative response [21].

Tumor markers could be used to differentiate chronic pancreatitis and pancreatic cancer. CA 19-9 was once used for this purpose, however due to its' low specificity and sensitivity this purpose was forgotten. Despite the fact that CA 19-9 is not used for surveillance in chronic pancreatitis, it can be helpful in families with hereditary pancreatitis [22].

OTHER TUMOR MARKERS

Cancer Antigen 125 (CA 125) is a glycoprotein most frequently used in the diagnosis, screening and prognosis of ovarian cancer, but with a very low sensitivity and specificity especially in early disease. It can have elevated values in non-gynecologic cancers such as: colon, liver, gallbladder cancer [4,8].

Carbohydrate Antigen 72.4 (CA 72.4) is a serological tumor marker used as a specific predictor for clinical recurrence in patients with gastric and colorectal cancer that undergo surgery and to follow up the treatment [23,24]. CA 72.4 with values higher than 7 IU/mL postoperative are associated with a worse prognosis, higher risk of recurrence and higher death risk. Studies show that in stage II colorectal cancer this tumor marker discriminates better than CEA the patients that will relapse or die from those with a favorable prognosis [25,26].

Chromogranin A is a protein contained by the neuroendocrine tumor cells. Elevated values can be encountered in a number of benign and malignant diseases. When referring to gastrointestinal disease we can find high values of chromogranin A in: carcinoid tumors of the gastrointestinal tract, pancreatic neuroendocrine tumors, colon cancer, hepatocellular carcinoma, pancreatic adenocarcinoma, liver cirrhosis, chronic atrophic gastritis, inflammatory bowel disease, and others. Chromogranin A has been associated with treatment response and might have prognostic value in neuroendocrine tumors [4,27].

CONCLUSION

Tumor markers remain a helpful tool in different afflictions. *AFP* is now considered the surveillance test of choice along with ultrasound in hepatocellular carcinoma. *CEA* is not used in the diagnosis of colorectal cancer, but in the prognosis and follow-up after curative surgery. *CA 19-9* is especially useful in the diagnosis pathway of cholangiocarcinoma in patients with PBS. Moreover, values over 1000 IU/ml are highly suggestive for cancer.

Air MEDEVAC in case of multiple casualties – The experience of civilian-military cooperation in RoAF

Dragoș C. Tudose[1], Daniel Nică[1]

Abstract: *Introduction: Starting September 2010 in Romania was created the Military Emergency Medical Service (SMMU) by the Ministry of National Defense, which has as main mission to provide first aid and save the lives of military personnel during military operations using special equipped MEDEAVC aircraft. Nationwide exist the national emergency system which operates thru 112- SMURD acting in support of the civilian population. In case of accidents with multiple victims the experience has shown the need for collaboration between the two systems, in order to save lives. In the last 5 years there has been an increasing Airlift missions (MEDEVAC) with multiple victims executed by joint civil-military medical teams using military aircraft.*

Material and methods. This paper provides a review of the most important aspects of particularities, advantages and disadvantages of this type of medical transport using the MEDEVAC missions based study carried out by the Air Force in recent years.

Results and conclusions. Performing these tasks presents challenges to mission planning, use of medical equipment and procedures, command-control system, exercise programs jointly joint medical teams and, of course, managing a large number of patients in flight.

The large number of patients transported safely and in the shortest time, regardless of weather conditions recommends this type of medical intervention.

Given the Romanian military presence in various theaters and that NATO strategic medical evacuation is a national responsibility, the capacity of air transport in case multiple casualties is a priority.

INTRODUCTION

Starting September 2010 in Romania the Military Emergency Medical Service (SMMU) was created by the Ministry of National Defense, which has as main mission to provide first aid and save the lives of military personnel during military operations using special equipped MEDEVAC aircraft. Nationwide exist the national emergency system which operates thru 112 emergency number – SMURD (Serviciul Mobil de Urgență, Reanimare și Descarcerare; Mobile Emergency Service for Resuscitation and Extrication) acting in support of the civilian population. In case of accidents with multiple victims the experience has shown the need for collaboration between the two systems, in order to save lives. In the last 5 years there has been an increasing Aeromedical evacuation missions (AME - MEDEVAC) with multiple victims

---

[1] 90th Airlift Base Romanian, Romanian Air Forces

executed by joint civil-military medical teams using military aircraft.

This paper provides a review of the most important aspects of particularities, advantages and disadvantages of this type of medical transport using the MEDEVAC missions based study carried out by the Romanian Air Force in recent years.

Performing these tasks presents challenges to mission planning, use of medical equipment and procedures, command-control system, exercise programs jointly joint medical teams and, of course, managing a large number of patients in flight.

The large number of patients transported safely and in the shortest time, regardless of weather conditions recommends this type of medical intervention.

Given the Romanian military presence in various theaters and that NATO strategic medical evacuation is a national responsibility, the capacity of air transport in case of multiple causality is a priority.

In this modern time beside the classical war conflict we are facing more and more new challenges like mass causality due to terrorist attacks, car accidents, fire and explosions in our civilian day by day life.

Due to financial and personnel restraints, neither one of the 2 system, civilian or military one, can properly face by itself this kind of incidents and it's just a question of time until the number of patients will overwhelm the capability and capacity of each system.

In Romania 2 systems coexist for Aeromedical Evacuation: the civilian SMURD (Mobile Emergency Service for Resuscitation and Extrication) using 8 EC135 helicopter and 1 Piper PA-42 Cheyenne III airplane and the military system under de MoD/RoAF command with 6 IAR 330 Puma helicopters and 1 C27J Spartan airplane. The drawback of the civilian system is that there aircraft don't fly at night and in severe meteorological condition. In the military one we don't have enough emergency medical personnel to cover 24/7. So this is the basis on which we start cooperation.

Due to the fact that national evacuation it's a civilian responsibility the military AME assets may be used to augment civil capability in 2 ways: Military aircraft assets with civilian medical crew and Military aircraft assets with mixed civilian-military medical crew.

Military aircraft used in this type of missions are:

● IAR 330 Puma MEDEVAC helicopter: fully equipped as an intensive care unit can carry up to 3 critically ill patient, in all-weather condition day or night with a range of 500 km;

● C130 Hercules has a maximum capacity of 74 stretchers with a range of 2000 km and have been use for years for CASEVAC missions from Iraq and Afghanistan;

● C27 Spartan: the newest and most modern aircraft from RoAF fleet can carry maximum 24 stretchers with autonomy of 6 hours and 2500 km. The characteristic of this aircraft is the possibility of carry 2 special ICU modules with dedicated monitor, ventilator and O2 capability.

Another characteristic is the MEDEVAC pressurization mode in which the aircraft will maintain the cabin pressure at ground level until flight level 130 (4000 m) in order decrease the hypobaric stress on the patient.

The last 6 years statistics show that from a total of 53 MEDEVAC missions with RoAF aircraft 15 (28.31%) where missions with multiple patients with a total of 100 patients (72.46%). The vast majority of this missions were made with C27J Spartan (12 – 80%), 2 with C130 Hercules (13.33%) and only 1 using helicopters (6.66%). That can be explained by the fact that the IAR 330 Puma helicopters can carry only 3 stretcher patient but at this load the space is severely limited. Another factor was the meteorological condition. This type of mission with multiple patients is used on longer distances (more than 300 km) and this is why the fix wing aircraft are used more (speed and distance advantages).

Messaging and alerts: because the civilian medical system can't put on alert the RoAF assets the messaging system goes like this: when somewhere in Romania an accident is happening the initial receiving medical facility contact the secondary or tertiary medical center if the complexity of the injury require a higher level of medical treatment. If the patients or patients are accepted for transfer then the medical coordinator of SMURD send an aeromedical evacuation request to CNMC (National Command Military Centre) who pass it to RoAF COA (Air Operation Component). At this level the Aeromedical Evacuation Officer have an up-to date image of the position, availability and the response time of each aircraft. The decision is made about which type of aircraft (airplane or helicopter) shall be used and the alert message is scrambled.

The particularity of multiple air MEDEVAC mission is that because the number of patients and the diversity of pathology the necessary medical equipment and the component of the medical team on board must be carefully planned on very short notice.

The military medical crew consists normally in 1 or 2 flight surgeons (medical officer, permanent working in an air base, having 1 year course in emergency medicine, 6 month training in aviation medicine, fit to fly according with the medical standards of the National Institute of Aviation Medicine) and 2 to 4 flight nurses (3 years degree in nursing after graduating Nurse College, 6 month training in emergency medicine, fit to fly) but in case of multiple cases this crew can or must be updated with ICU specialist or neonatologist accordingly to the medical need (in June 2012 MEDEVAC mission from Bucharest, ROU to Hanover, DEU with 3 children from 7 day to 3 years old with cardiac malformations in with the crew was upgraded with 1 neonatologist and 2 nurses beside the flight surgeon and the flight nurse from RoAF).

In term of medical equipment due to the national standardization there are no compatibility problems in term of coupling power tension or O_2 pressure. The only real challenge is how to be able to get all the necessary equipment in time and in the right quantity (in July 2008 after a explosion in a Gheorghieni local wood factory we accomplished a MEDEVAC mission for 10 severely burn patients, 2nd 3nd and 4th degree burns, all respiratory assisted and mechanically ventilated so the problem was how to have 10 ventilators and 10 multifunction monitors in that plane in less than 2 hours.)

AEROMEDICAL ASPECTS

Hypoxia is the greatest threat to anyone flying. Physiological effects of hypoxemia can be detected in healthy individuals at lower altitudes of 3000 m but more rapidly in certain patients. It occurs due to changes in ambient pressure. Cabin pressurization reduce this problem especially airplanes, but patients with respiratory failure may be at risk for hypoxemia current cabin altitude achieved. Adjusting the fraction of inspired oxygen to maintain the partial pressure of inspired oxygen constant throughout the mission is a technique useful clinically for prevention of hypoxemia. The wide availability of pulseoximeter decreased incidence of hypoxemia in the MEDEVAC missions with early recognition.

Accelerations: Acceleration or deceleration is a vector quantity, having both magnitude and direction. For this reason, the correct positioning of the patient in the idea to limit acceleration-induced forces sustained should be carried out. Acceleration forces that are experienced in helicopters or planes during routine operations (due to flight techniques and procedures ensuring low range of acceleration forces during MEDEVAC missions) tend to be small in size or as great as those observed in terrestrial transport vehicles.

Volume of gas: ambient pressure decreases with increasing altitude. Pressure changes with altitude and the change can affect a number of medical devices and patients. Contrary to common belief, cabin pressurization does not eliminate the problem. Pressurization allows a comfortable flight altitude manned which could not otherwise be achieved, but in general, not altitude from sea level, and thus, the equipment and the patient will be exposed to a pressure change. Any gas enclosed in a structure therefore becomes a concern. Air trapped in the sinuses, for example, can expand and cause discomfort and equipment (air-filled cuffs) can be damaged or can injure patient with the change altitudes.

Humidity: Humidity is a particular concern in fixed-wing missions because cabin air is taken from the rarefied atmosphere outside, and even in pressurized aircraft and when heated may contain very little moisture. This can lead to dryness and discomfort of the patient secretions during flight.

Noise: Modern aircraft produce quite a lot of noise. In most aircraft cabins is pretty quiet for conversation and patient evaluation but cabins of helicopters are so loud that exclude pulmonary auscultation. Soundproofed helmets and intercom systems are needed.

Vibration: Vibration is a form of repetitive alternative motion. The two major sources of vibration during MEDEVAC missions are powerplant and turbulence of the air moving aircraft. The vibrations cause discomfort and fatigue to patients and also to medical team, and are transmitted to medical equipment in flight and can be the source of errors and monitoring failures.

CONCLUSION

The Multiple victim accidents are a REALITY and the transport of those patients to an adequate level of care facility is a NECESSITY. Air medical transport put additional stress on patients (fear of flying, physical discomfort), on medical staff (unconventional and insufficient workspace with great limitation regarding medical equipment and medication and the impossibility to receive advice and expertise) and on medical equipment (operating in a vibration, pressure and temperature differential environment). Influence appears to be greater for the transport helicopters and in case of multiple patients.

Air medical evacuation missions with multiple victims require: rigorous planning, exercises (based on realistic scenarios) and resources (time, money, personnel, equipment).

Romanian Air Force aircraft equipped MEDEVAC are on alert 24/7 and the training of medical staff allow prompt intervention in case of accidents with multiple victims;

Civil-military intervention can be a solution for those situations, on the condition of legislation harmonization in order to provide fast and efficient mobilization of resources and cooperation between military and civilian institutions.

Finite element analysis of a modified short hip endoprosthesis

Augustin Semenescu[1], Florentina Ioniță Radu[2], Ileana M. Mateș[2], Petre Bădică[3], Nicolae D. Batalu[1]

Abstract: *A finite element simulation of the mechanical static features for a modified short hip endoprosthesis was performed. The corkscrew-like femoral stem was modified introducing more turns of the thread. By such an approach it is expected that for some cases the mechanical fixation of the prosthesis to the bone will be improved or the use of the cement for bonding is not necessary. Our scenario was estimated for titanium and stainless steel, and both materials show good safety factors. Mechanical stress is expected to be distributed more uniform in the bone for the new design with more turns of thread.*

Keywords: *modified short hip endoprosthesis; design; finite element analysis; titanium; stainless steel*

INTRODUCTION

The increase in the average life expectancy rose the age at which different surgical interventions are performed. For example, the total replacement of the hip is made on a typical patient of 60-80 years old, and often patients are older, in some cases even over 100 years old. The primary hip intervention can be followed by several revision surgeries [1,2,3]. This is a reason for designing modular endoprosthesis, where damaged parts can be easily replaced.

A short femoral stem is recommended for patients where the femoral bone allows a minimal resection, and the bone structure has enough mechanical resistance to support the stress induced by implant [4]. A positive aspect of our design consists in screwing the implant into the bone, avoiding its hammering [5,6] that has a high risk of femoral neck fracturing. The prosthesis has a cylindrical metallic body, with an exterior thread, continued with a truncated sleeve, and ended with a junction neck (Figure 1). Inside of the implant there is a hexagonal hole for the insertion of a torque screwdriver (not shown). The distribution holes are built-in and they are intended to be used to spread the cement for fixation after the stem is screwed in the bone.

In this work a modified design is proposed. Namely, more turns (7 instead of 3) [7] of the screw-component of the endoprosthesis are considered. Expectations are to obtain an improved implant-bone fixation and a more uniform distribution of the forces that will allow a longer lifetime with less revision surgeries: it is well known that after about 10-15 years the prosthesis loosens and a replacement may

[3] National Institute of Material Physics

be required [8]. For certain cases it is thought that our improved design may also provide a cement-free fixation. Finite-element analysis is used to estimate mechanical features of the prosthesis with the modified design. Two materials, titanium and stainless steel are considered.

MATERIALS AND METHODS

1. CAD design and materials properties

The endoprosthesis was designed [9] in Inventor Professional 2016, and the materials properties were assigned from the software database.

The proposed materials for the endoprosthesis are titanium and stainless steel (Table 1). Materials are considered isotropic and linearly elastic.

2. Mesh settings

All the settings are detailed in [6]. The total number of the resulted elements was 1,694, and the total number of the nodes was 3,287.

Table 1. Mechanical properties of materials used in simulation.

Material	Density [g/cm^3]	Young's Modulus [GPa]	Poisson's ratio	Shear Modulus [GPa]	Yield strength [MPa]	Tensile strength [MPa]
Titanium	4.51	102.81	0.36	44	275.6	344.5
Stainless Steel	8.00	193.00	0.30	86	250.0	540.0

3. Boundary and loading conditions

The endoprosthesis, either the initial or the modified design, is considered fixed on its stem, thread, and under the supporting disk for the scenario when using cement (Figure 1.a, blue region). For the cementless approach only the thread and the part under supporting disk are considered fixed. (Figure 1.b, blue region).

A load of 6000 N magnitude is analyzed, as the most unfavorable case [7]. Both scenarios are studied without the implant/cement/bone interactions.

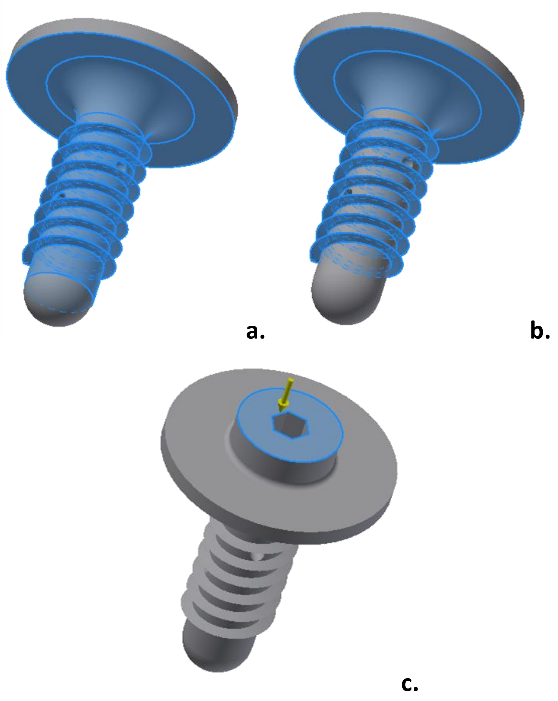
A static compression load is distributed on the upper surface of the disk (Figure 1.c, blue region denoted with an arrow). The safety factor is based on the yield strength.

RESULTS AND DISCUSSION

The simulation results are shown in Table 2 and Figures 3, 4 and 5. The differences between the initial and modified designs are not significant, for selected materials, titanium and stainless steel.

A longer thread suits better for a cementless fixation (Figure 1.b), due to the larger contact area. For the stainless steel, the analysis is shown in Figure 5. The static finite element analysis shows no significant differences when compared to the "cemented" scenario.

Figure 1. Fixed constrained areas of the modified short femoral endoprosthesis: (a) for "cemented", and (b) "cementless" scenarios. (c) Selected area for force distribution.



This approach confirms that the new design does not affect the mechanical behavior of the endoprosthesis. A longer thread is also expected to provide a better stress distribution in the femoral neck and further studies are required.

Table 2. Maximum displacements, maximum Von Mises Stress, and the minimum safety factor for a 6000 N load and different threads.

CONCLUSIONS

A modified short hip endoprosthesis design is proposed as a better solution than the previous one, where a fixation using cement is considered. The new simple design consists in a longer thread that increases the friction force between endoprosthesis and bone by increasing the contact surface. The finite element analysis shows that the modified design does not affect the mechanical behavior. This design may allow, in some cases, a cementless fixation. Further tests are necessary to confirm our results.

Optical “biopsy” in laryngeal cancer detection

Romeo Costin[1], R. Hainăroșie[2], V. Zainea[2], Corneliu Romaniţan[1], A. Meiuş[1]

INTRODUCTION

Squamous cell carcinomas of the larynx is by far the most frequent malignant tumor of the head and neck region, representing 1-2% of all malignancies diagnosed world-wide. Treatment results of early cancer are not unfavorable: for the reported 5-year-survival rate of Tis, T1, T2 laryngeal cancer patients ranges from 80 to 90% [1]. At present, indirect laryngoscopy is widely used for the evaluation of laryngeal cancer and precancerous lesion, while direct laryngoscopy under general anesthesia with biopsy remains to be the gold standard.

The expression optical “biopsy” has entered into usual speech among researchers in the domain of biomedical optics. In fact this joining of terms is a paradox, because “biopsy” refers exactly to the removal of tissue, while the signification of “optical” is that tissue is not removed. The real meaning of this expression consists in amount of optical measurements mediated by optical fibers which allow the physician to perform an instant tissue diagnosis in vivo, in situ, noninvasively and in real time, previously possible only by using histological analysis. The main reason of this is to avoid the surgical removal of biopsy tissue samples.

These refined optical techniques go beyond standard endoscopic methods by offering improved image resolution, contrast, tissue penetration and delivering biochemical and molecular knowledge about mucosal disorders. For some endoscopic application, for which “random” biopsies are repeatedly taken to discover premalignant or early malignant lesions, optical measurement could enable “guided biopsy”, with increased probability for sampling a diseased site, reducing the number of tissue samples. Thus, additional purpose is certified by the potential for reduced health-care costs by eliminating unnecessary histology. Besides, the instant diagnostic information can reduce the emotional trauma to the patient awaiting an answer [2].

Recent technological advances in fiber optics, light sources and detectors have stimulated the tremendous development of many optical methods that promise to notably improve capability to visualize and evaluate human epithelium in vivo [3,4,5]. Some of these techniques are used for detection of laryngeal cancer: fluorescence spectroscopy, optical coherence tomography, narrow-band imaging, contact endoscopy and confocal endomicroscopy. This review describes the basic biophysics of light-tissue interactions, evaluates the strengths and weaknesses of each technique and explores clinical and preclinical evidence for each approach.

OVERVIEW

Fundamental parameters that characterize tissue

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest
[2] Institute of Phonoaudiolology and ENT Functional Surgery “Prof. Dr. D. Hociota”, Bucharest

optics in terms of radiative transfer are: absorption coefficient, scattering coefficient and anisotropy and measuring those constitutes a central issue in biomedical optics [6].

a. The absorption coefficient (μa) determines the probability of absorption events for a photon that propagates in tissue. Absorption occurs due to coupling of photons energy at a particular frequency with electronic or vibrational transitions energy. Depending on the spectral field, absorption is caused by:
- Cellular DNA and protein (amino acids and nucleic acids) in ultraviolet;
- Specific chromophores (hemoglobin, melanin, etc.) in visible;
- Water, OH and amine infrared.

b. Scattering coefficient (μs) determines the probability of a photon to be scattered during propagation. Scattering is caused by fluctuations of the refractive index of the environment in microscopic scale (ultra-structural heterogeneity) such as water-lipid interfaces membranes inside the cell and surrounding cells and fibers of collagen in the extracellular matrix. We can say that the absorption properties of tissue are tied to tissue biochemistry, while the scattering ones are related to its morphology.

c. Anisotropy (g) is the average cosine scattering angle and weighted the scattering coefficient effectiveness.

d. Alongside the three basic parameters, in medical practice, are also used: attenuation coefficients (total and effective); reflection; the refractive index; reflectance.

Cheong et al [7] realized (1990) a comprehensive compilation of optical tissue properties (absorption coefficients, scattering, total and effective mitigation and anisotropy for different biological tissues at a variety of wavelengths). They concluded that for a specific tissue, large areas of these parameters are frequent, indicating the sensitivity and vulnerability of such measurements to sample variation, detection equipment, boundary conditions and adopted light propagation model. Confidence in the obtained values can be compromised by any of these factors. After 1990, numerous studies have improved this knowledge, creating optical exploration methods that will be presented below.

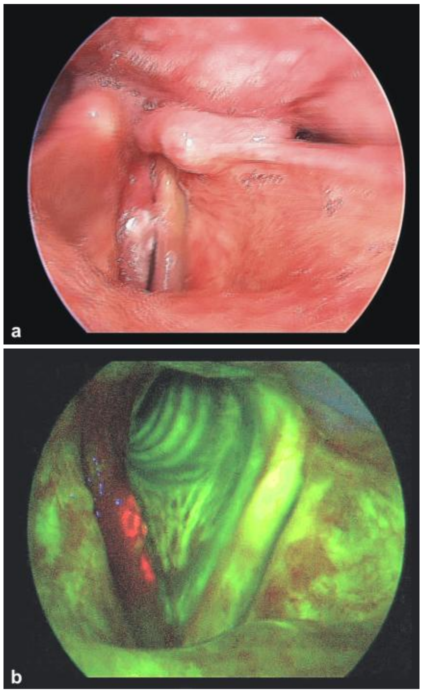
1. Spectroscopy

1.1. Autofluorescence endoscopy (AFE)

Autofluorescence was first observed by Policard [8] in 1924, but Alfano [9] demonstrated in 1984 differences in spectral profiles of cancerous and normal tissues. In the last decades, this technique was used for screening in early detection of cancers of upper- and lower-GI tract and also lower-airway, and recently it was used in identifying precancerous and cancerous lesion [10].

Tissue autofluorescence is based on the presence of endogenous fluorophores, which emit visible green light on appropriate excitation. This involve structural proteins (collagen, elastin) mainly located in the submucosa, but also keratin, porphyrin and enzymes of the respiratory chain such as nicotinamide adenine dinucleotide and flavin adenine dinucleotide within the epithelium [11].

Figure 1: Squamous cell carcinoma of the right vocal fold: White light endoscopy (a); Autofluorescence endoscopy (b) [13]



Because of an altered metabolism in tumor cells, premalignant and malignant tissues show a decreased quantity of fluorophores. Moreover, epithelial thickening prevents the excitatory blue light from reaching the submucosa. Both mechanism results in a loss of autofluorescence, with a color change from green to red-violet [12].

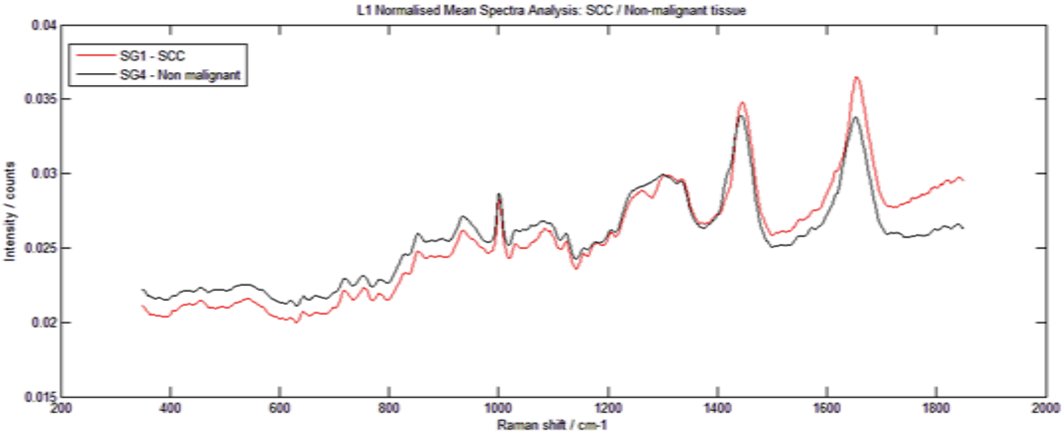
In AFE, healthy mucosa and benign lesion covered by normal epithelium (polyps, nodules, cysts, Reinke's edemas) present green color (no loss of autofluorescence). Scar tissue following surgery or radiotherapy shows a violet color; the same aspect is found in hyperplasia and chronic inflammation.

AFE can be used in early detection of premalignant and malignant lesions, in guided biopsy and oncological follow-up. This technique can only detect changes on epithelium, but not in the deeper structures [14].

Many studies have found that AFE has a better sensitivity and specificity in detecting laryngeal malignant changes than the classic white light endoscopy (WLE) [15,16,17]; a meta-analysis made by Kraft and co. in 2010 concluded: in identifying precancerous and cancerous lesions of the larynx, sensitivity (91% vs. 73%), specificity (84% vs. 79%) and accuracy (88% vs. 77%) of AFE were superior to WLE alone[18]; false-positive diagnoses result from chronic laryngitis, teleangiectatic polyps, granulomas[19] and papillomas; false-negative diagnoses are found in extreme hyperkeratosis, necrosis and inflammation [20,21].

There is a variant of this method involves the study of autofluorescence laryngeal mucosa after topical application of aminolevulinic acid, preferentially captured by the cancer cells, that became colored in orange-red (because protoporphyrin IX), while normal mucosa appear green [22].

Figure 2: Normalized mean and difference spectra for squamous cell carcinoma and non malignant tissue in larynx [26].



1.2. Raman spectroscopy

This method involves an effect whereby a small portion of tissue scattered light has a different frequency from that of the incident beam, with an equal amount of vibration frequencies of the molecules in the tissue; the effect is very weak, but with laser, it is possible to study the movements of rotation and vibration of molecules [23]. From the received signal, the percentage of biological molecules can be extracted in samples, such as collagen, elastin, beta-carotene, cholesterol (fig.2).

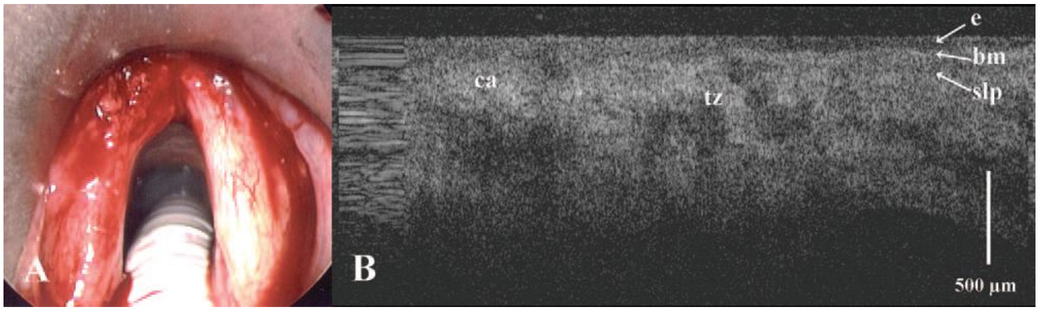
Introduced in medical practice in 2000, Raman spectroscopy is used to differentiate normal laryngeal tissue of precancerous and cancerous lesions [24]. Some authors publishing studies that indicate sensitivity between 70-90% and specificity in differentiating between normal tissues/malignant between 85-95 % [25].

2. Optical coherence tomography (OCT)

OCT is a modern method of investigation, in high resolution, mainly used in ophthalmology. It is derived from low coherence optical interferometry and uses non-ionizing optical radiation in the near infrared field.

OCT allows measurements in real time, in situ, with resolution up to 10 times higher than conventional radiology (CT, MRI), making it possible to identify microscopic tissue structures (villi, glands, crypts, blood vessels). Despite this exceptional resolutions (1-2 µm), the method is limited by the very low degree of depth (penetration of tissue) of 1-3 mm [27]. Articles published in the past decade shows that it can be used to detect an epithelial membrane rupture and overcoming of the laryngeal carcinoma or epithelial thickness measurement (normally between 98-185 µm, about 500 µm in hyperkeratotic lesions) [28].

Figure 3: T2 squamous cell carcinoma of the left vocal fold; (A) Endoscopic photograph. (B) Optical coherence tomography image demonstrating normal epithelium with an intact basement membrane on the right of the image, and invasive cancer with increased backscattering and loss of the basement membrane on the left. A transition zone is seen between these two areas. Note the area of motion artifact on the left of the image (bm-basement membrane; ca-invasive cancer; e-epithelium; tz-transition zone; SLP-superficial lamina propria) [29]



3. Narrow band imaging (NBI)

It is a modern endoscopic technique for investigating the vocal cord that uses certain wavelengths of light to improve the viewing of epithelial and sub epithelial microvascular pattern. They are using wavelengths of 415 nm (blue) and 540 nm (green), which are absorbed by hemoglobin, causing epithelial microvasculature to be colored in brown and become visible. The obtained images can be improved and recorded by using a HD (High-Definition) video system [30,31].

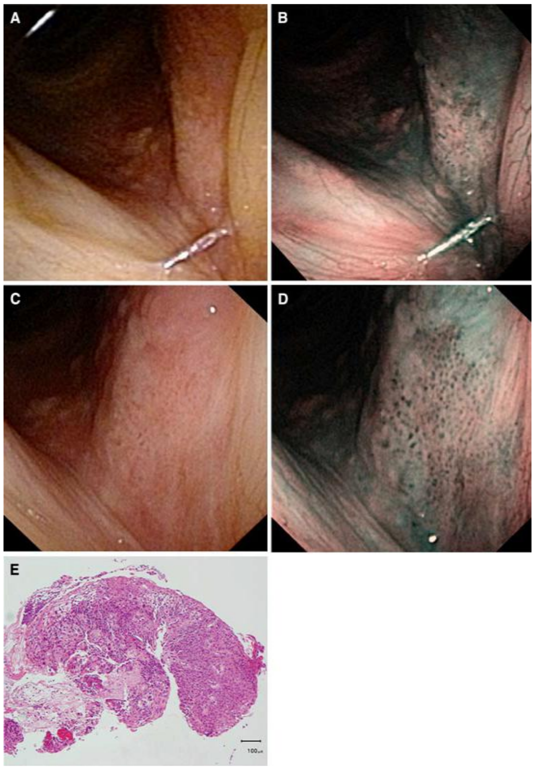
Neoplasia suspicion rises when on a brownish area, well-marked, is observed thick dark spots and/or tortuous course of the microvasculature, or more, a hypertrophic blood vessel that branches in small vascular loops [32,33]. There are studies that demonstrate that this optical method can even make the difference between neo-vessels specific to carcinoma and the ones altered by post-radiation inflammation [34].

The method was originally used for early detection and monitoring post-surgery esophageal [36], and tracheobronchial [37] neoplasm lesions, but recent studies show that is gradually earning supporters using it for the same goals at the larynx [38,39] (good results in subglottis injuries). Thus, Japanese authors demonstrate that narrow-band imaging has a sensitivity of 91.3% and a specificity of 91.6% [40], in laryngeal cancer lesions, while a team from Italy (Brescia) reports 90% specificity and 98% sensitivity [41].

Another recent study [42], multicenter, prospective, randomized, which included patients with esophageal cancer and pharyngeal and laryngeal cancer, showed that narrow-band imaging compared with conventional endoscopy detected a higher number of superficial carcinomas synchronous in both locations, making them the authors to conclude that this method could be the standard examination for early detection of superficial cancer in those localizations.

But the interpretation of the images must be made by an ENT specialist with a good experience, to avoid false negative or false positive. Also false negative may occur on lesions where the keratin layer has a greater thickness.

Figure 4: A. Conventional white-light image of the larynx. The left subglottic region is displayed slightly reddish. B. NBI image of the same site as a. Demarcated brownish area is seen in the left subglottic region surrounded by green area. C. Close white-light view of a. D. Close NBI view of b. There are scattered brown spots in the lesion. E. Histopathologic evaluation of the biopsy specimen revealed moderately differentiated squamous cell carcinoma of the larynx [35].



4. Confocal endomicroscopy

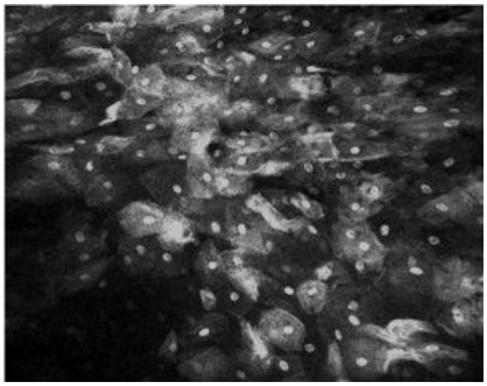
This technique is introduced into medical practice in 2004 by R. Kiesslich for in vivo diagnosis of colorectal cancer[43]. The principle of the method consists in illuminating the examined tissue with a laser wave of 488 nm which allows viewing epithelium in depth up to 250 µm. For a better image quality is given intravenously a contrast substance (fluorescein). The examination is made simultaneously with both endoscopic and endomicroscopic, acquiring images to identify the characteristics of epithelial cells (size, shape, appearance of the nucleus) near the basal membrane [44].

The limitation of this method is shallow penetration (250 µm), knowing that the cancer epithelial thickness can reach 500-1000 µm, being unable to view the membrane. Also it requires a pathologist with experience.

Introduced recently in Otolaryngology, there are still no studies on a large number of cases, but those in the gastrointestinal field [45,46] give high hopes for the future of this method.

There is a pilot study [47] clearly demonstrates the possibility to detect dysplastic cells near to the basal cell layer and within the subepithelial space in lesions with small leukoplakia (thin keratin layer). These results can have an impact on microlaryngoscopy to improve the precision for biopsy and on microlaryngoscopic laser surgery of the larynx to identify the margins of the pre-malignant lesion.

Figure 5: Confocal endomicroscopy image of the human supraglottis captured in vivo following topical application of 0.05% acriflavine hydrochloride [48]



5. Contact endoscopy

Contact endoscopy is another novel noninvasive optical diagnostic imaging method that allows in vivo and in situ examination of the cellular architecture of the superficial layers of the mucosal epithelium. Magnified images are obtained using Hopkins' rod-lens endoscope placed on the surface of the dye stained mucosal tissue. This method allows evaluation of precancerous and cancerous lesions in vivo and has significant potential in the histopathologic diagnosis of many suspicious head and neck mucosal lesions without tissue biopsy. The first reported use of CE in otolaryngology head and neck surgery was by Andrea et al. as a diagnostic tool in the evaluation of various pathologies in the larynx in the 1990s [49]. They were able to visualize and diagnose laryngeal mucosal pathology from the magnification of vocal fold epithelium and microvasculature during microlaryngoscopy after staining the vocal cords with methylene blue dye.

Few members of our group [50] have systematically drawing vascular changes of the vocal fold, with clinical and pharmacological applications. They demonstrated the changes of microvascularity, occurring since stage of hypertrophic chronic laryngitis (hypervascularity with dilated vessels, but parallel to the free edge of the vocal fold) till the carcinomatous lessions (with hypervascularity and areas of keratin, changes of the archaeological and cytological parameters: **U**niformity of the cellular-field, **R**atio (nucleus/cytoplasm), **S**ize and **S**hape of the epithelial cells [51].

There are more advantages of contact endoscopy. Most significantly, it offers a noninvasive, quick, and repeatable in vivo evaluation of the cytological architecture while avoiding the need for an invasive biopsy and its associated risks. CE provides immediate results, with the possibility of examining many mucosal areas in a short time. CE can also assess a wider surface mucosal area, providing more information than a selected histological section taken by biopsy [52]. It also avoids tissue damage and alteration of cellular architecture which may occur in the biopsy and histological preparation. Subsequently, this results in a dramatic improvement of the diagnostic yield of the biopsy. Other potential roles of CE include the rapid diagnosis of benign and malignant mucosal lesions in an outpatient or operating room setting, surveillance, guided biopsies, and intraoperative evaluation of tumor resection margins. Despite its advantages, CE does have its limitations. Most notably, CE can only evaluate the most superficial cell layer of the mucosal epithelium. This is most likely due to a number of factors including (i) poor penetration of methylene blue which only stains a few superficial layers, (ii) short focal distance of the scope (i.e., CE can only assess to a depth of 80 um at 60x magnification and 30 um at 150x magnification), and (iii) optical artifact at high magnification due to glare from light reflected from cells not in focus. The lack of depth of penetration prevents the evaluation of important histological information especially when vertical extent of dysplasia is crucial in distinguishing the different grades of dysplasia from carcinoma in situ and invasive carcinoma. As a result, these factors could affect the sensitivity of CE, thus accounting for some of the false negative diagnostic results noted by authors. The potential impact of CE missing a malignant lesion needs to be taken into consideration if this technology is to one day substitute histopathology. Future investigation into better penetrating dyes, advances in digital optics, and image enhancements will eventually allow better vertical staining and increased resolution of the deeper cell layers which would translate CE in becoming a much more sensitive and accurate diagnostic tool.

Detection of epidermoid squamous-cell carcinoma by laser induced autofluorescence – preliminary results

Romeo Costin[1], Tatiana Tozar[2], V. Zainea[3], Ruxandra Pîrvulescu[4], I. R. Andrei[2], R. Hainăroșie[3]

Abstract: *Epidermoid squamous-cell carcinoma is by far the most common malignant tumor of larynx (95-96%), representing 1.6-2% of cancers in men and 0.2-0.4% of malignancies in females, with a world growing incidence and a slight dominance in urban areas. By exposing cells and tissues to UV light, the excitation of naturally occurring chromophores occurs in part by non-radiative deactivations, in part via fluorescence emission. Using laser induced autofluorescence (LIAF) in natural tissues not impregnated with photosensitizers as a noninvasive autofluorescence technique for both diagnosis and intraoperative assessments of laryngeal cancer we can improve the tumor malign identification in vivo. A total of three laryngeal biopsies (i.e. three pairs of tissues, each pair containing a healthy and a tumor tissue sample extracted from the same patient) were considered in this study. The samples were collected from patients previously diagnosed with stage T3 laryngeal carcinoma. Immediately after the surgery fragments of normal tissue and neoplastic tissue were collected, fragments of which later, after freezing, were sectioned in 25-30 µm thickness slices and stretched to quartz slides. All samples were subjected to controlled laser irradiation using a pulsed diode laser (λ=375nm, pulse width=87ps, frequency 31MHz) and the autofluorescence and its lifetime were collected using two optical fibers (inner diameter 400µm and 1500µm, respectively) positioned in a 45° geometry. The signals were recorded using a spectrograph and a photo-sensor module, the output of which was fed to a digital oscilloscope.*

We assessed the impact of laser induced autofluorescence and autofluorescence lifetime measurements in order to identify the differences between healthy and tumoral laryngeal tissue and outlining them, in terms of differences between the laser autoinduced fluorescence averaged intensity. The results determined the usefulness of laser induced spectroscopy in the diagnosis of laryngeal squamous cell carcinoma, discriminating between the malignant and normal tissue by analyzing the differences in spectral autofluorescence intensity and autofluorescence lifetime.

INTRODUCTION

Cancer is a growing dilemma in the developed countries. Laryngeal carcinoma is the most common cancer of the head and neck. Epidermoid squamous-cell carcinoma is by far the most common malignant tumor of larynx (95-96%), representing 1.6-2% of cancers in men and 0.2-0.4% of malignancies in females, with a world growing incidence and a slight dominance in urban areas [1].The main risk factors are smoking, alcohol consumption, harmful dietary habits, exposure to the irritant chemical substances [2].

Early identification and pre-operative evaluation of laryngeal carcinoma and its precursor lesions are essential for function-preserving surgical treatment. Accurate determination of the site and extent of carcinomas is very important for planning therapy and establishing prognosis [3]. Attempts to optimize diagnostic methods to obtain more sensitive detection and precise description of laryngeal pathology remain a challenge for the otolaryngologist [4].

Microlaryngoscopy with biopsy is the standard diagnostic procedure for the detection of laryngeal carcinoma. Anyway, the microscopic view added to the palpation of the larynx is not always enough to the evaluation and precise description of precursor lesions. Some new techniques, like videostroboscopy, contact endoscopy, confocal endomicroscopy, optical coherence tomography, narrow-band imaging and fluorescence endoscopy have been developed to come up with the detailed examination and the histopatological information about mucosal lesions [5,6].

Fluorescence is a optical phenomenon of the light emission by some molecules after their excitation by the light at a particular wavelength. These fluorescent molecules are called fluorophores. Every fluorophore exhibits its characteristic absorption and emission bands whose shapes and positions of their maxima on the excitation and emission light wavelength axes depend on the physical and chemical properties of its nearest environments. The interest in the use of fluorescence in medical diagnostics has grown during the last decades. Fluorescence spectroscopy provides information on the biochemical and morphological aspects of different tissues [7].

The procedures using the fluorescence spectroscopy for the differential diagnosis of malignant lesions are based upon the differences in the autofluorescence emission due to the pathological changes of the tissue. These changes include the modifications of tissue architecture (tissue layer loss or thickening), light absorption and scattering by neovasculature, and the alterations of metabolic status of the tissue such as changes of the concentration and distribution of fluorophores [8]. As a result, recorded fluorescence emission spectra of cancerous lesions reveal differences in fluorescence intensity and fluorescence band shapes, when compared to healthy tissue.

MATERIALS AND METHODS

The spectroscopic measurements were investigated in three larynxes from laryngectomized cancer patients treated in ENT Clinic, Carol Davila Central University Emergency Military Hospital, Bucharest. Histological analysis of the tumor tissues revealed laryngeal epidermoid squamous-cell carcinoma (SCC) in both cases, stage T3 (Figure 1). Immediately after the surgery (total laryngectomy), the larynx was carefully washed in saline solution to remove any blood contamination.

After that, fragments of normal tissue and neoplastic tissue were collected, fragments of which later, after freezing, were sectioned in 25-30 µm thickness slices and stretched to glass slides (reconfirmed histological) and stored at -80ºC for further examination. All participants provided written consent to participate in the experiment. The study was approved by the local ethics committee.

Experimental setup (Figure 2) was performed using laser beam exposure of the samples a picosecond pulsed laser diode (Alphals, type PicoPower LD-375-50) emitting at 375 nm with 31MHz pulse repetition rate, 87 ps full time width at half-maximum laser pulses, and the average power of about 0.5 mW. A laser beam of 1.6x1.8 mm (elliptical) diameter was sent to the sample in double-pass vertical irradiation geometry through a 355 nm dichroic mirror and a totally reflecting mirror.

Two types of measurements on tissue samples were performed: laser induced autofluorescence (LIAF) and autofluorescence life-time. The autofluorescence signal was collected using two optical fibers positioned each, at 45° in the same plane with respect to the pumping laser beam.

Optical fiber
Optical fiber
XY manual stage
Acton SpectraPro 2750 spectrograph
Photo-amplifier Hamamatsu (rise time 0,5 ns)
Tektronix oscilloscope

The optical fiber with the core diameter of 400 µm collects the signal for LIAF spectrum analysis; another fiber of 1,500 µm collects the remitted signal for autofluorescence life-time analyses. The LIAF signals were recorded using a spectrograph (Princeton Instruments, type Acton SpectraPro 2750) with an optical resolution of 0.08 nm and; a photosensor module (Hamamatsu, type H6780-20) having 0.78 ns rise time, was used for LIAF life-time measurements and its output was fed to a digital oscilloscope (Tektronix, type DPO7254). The signal acquisition by spectrograph and photosensor module was synchronized with the laser pulse through a pulse delay generator (SRS, DG 535). During the LIAF measurements, the probe (sample and substrate/slide) was placed on a XY manual stage with a displacement resolution of 5 µm. Each type of measurement was performed collecting the LIAF signal from three different spots for each sample. For each healthy and tumoral tissue two slides with the same type of samples were prepared.

RESULTS

The LIAF spectra of the healthy and tumoral tissues are presented in Figures 3-5 and are compared in terms of peak intensity (*I*), Area (*A*) under fluorescence spectral distribution curve and ratio between the intensity and the corresponding full width at half maximum (*I/FWHM*) signal.

In case I, two healthy tissues of different thicknesses, 20 µm and 30 µm, were compared. Figures 3A and 3B presents the LIAF spectra of the three spots from the duplicate samples and Figure 3C shows the corresponding averaged spectra. The peaks of LIAF spectra are placed between 456 – 462 nm for the 30-µm tissue thickness and between 460-463 nm for the 20-µm tissue thickness. In Figures 3A and 3B are observed variations in peak intensity, area and I/FWHM and approximately the same values for FWHM. These variations are, dominantly and most probably, due to different concentrations of fluorophores in the samples. The comparison between the averaged spectra of 20 µm and 30 µm shows 11.4% autofluorescence intensity, a 9.5 % area and a 14.4% I/FWHM increase in 30 µm with respect to 20 µm case.

Figure 3. Case I. LIAF intensity for healthy tissue for different thickness: A) 20 µm and B) 30 µm; collected in three spots of the duplicate samples and the averaged spectrum; C) LIAF intensity of the averaged spectra from the 20 µm and 30 µm thickness samples.

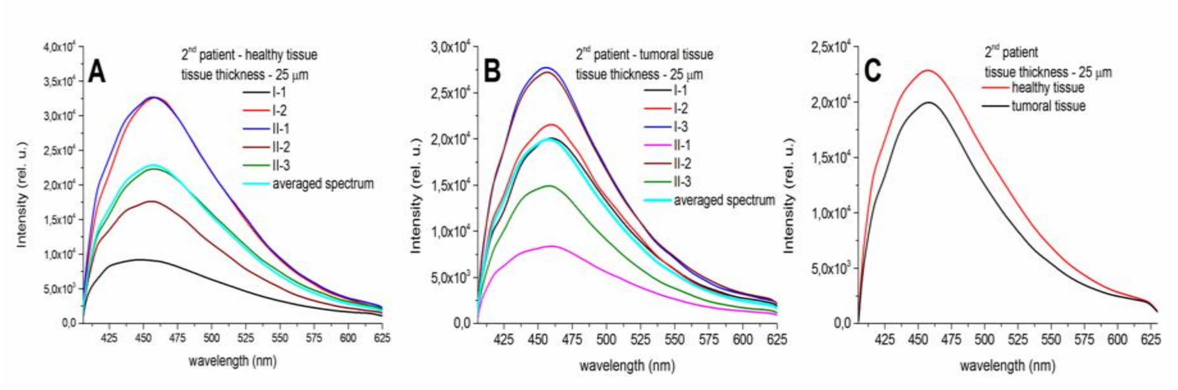

Figure 4. Case II. LIAF intensity for 25 µm tissue thickness: A) healthy and B) tumoral; collected in three spots of the duplicate samples and the averaged spectrum; C) LIAF intensity of the averaged spectra from the healthy and tumoral samples.

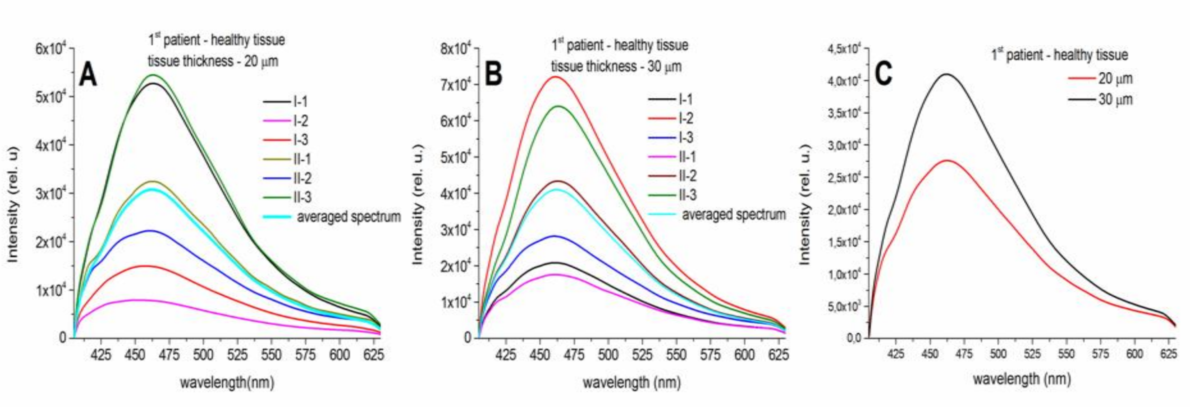


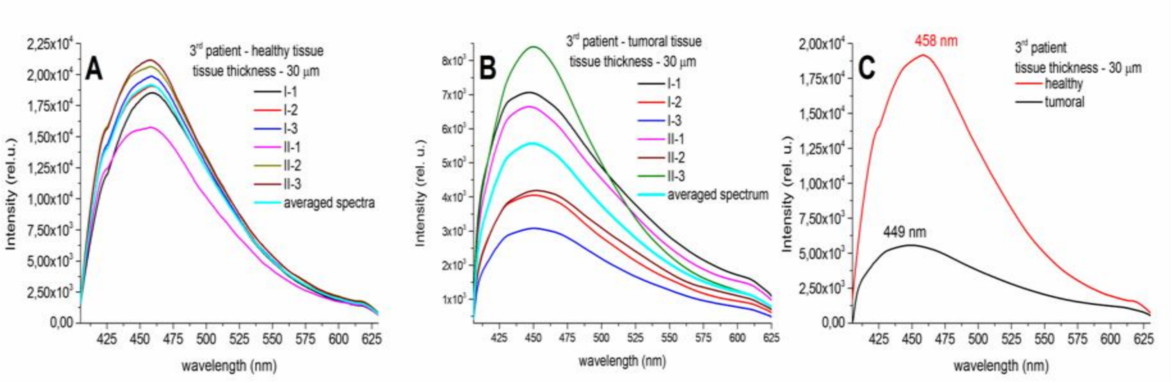
In case II, one healthy and one tumoral tissue of 25-µm thickness were analyzed. Figures 4A and 4B present the LIAF spectra of the three spots from the duplicate samples and the corresponding averaged spectrum (Figure 4C). The peaks of LIAF spectra are placed between 445 – 462 nm for healthy tissue and between 456 – 459 nm for tumoral tissue. In Figures 4A and 4B, are observed variations in peak intensity, area and I/FWHM and approximately the same values for FWHM.

In general, the maximum value of LIAF's intensity is smaller for the cancerous tissue (with 16.7%) than the healthy one. The area and the I/FWHM ratio of LIAF for cancerous tissue is also smaller than for healthy tissue (with 17.1% and 4.7%).

In case III, one healthy and one tumoral tissue of 30-μm thickness were analyzed. Figures 5A and 5B present the LIAF spectra of the three spots from the duplicate samples and the corresponding averaged spectrum (Figure 5C). The peaks of LIAF spectra are located between 457 – 458 nm for healthy tissue and between 456 – 459 nm for tumoral tissue. In Fig. 5A and 5B, are observed variations in peak intensity, area and I/FWHM, but smaller than those from case II, and approximately the same values for FWHM.

In Figure 5C, the maximum value of LIAF's intensity is smaller for the cancerous tissue (with 71%) than the healthy one. The area of LIAF for cancerous tissue is also smaller than healthy tissue (with 66.7%). At the same time, maximum spectrum for tumor sample is shifted to blue with nine nm (449-458 nm) than healthy tissue and the I/FWHM ratio decreases with 74.2% when comparing the healthy tissue with the tumoral one.

Figure 5. Case III. LIAF intensity for 30 μm tissue thickness: A) healthy and B) tumoral; collected in three spots of the duplicate samples and the averaged spectrum; C) LIAF intensity of the averaged spectra from the healthy and tumoral samples



The computed parameters based on the experimental data extracted from LIAF spectra for the 2nd and 3rd patient healthy and tumoral tissues are shown in Table 1.

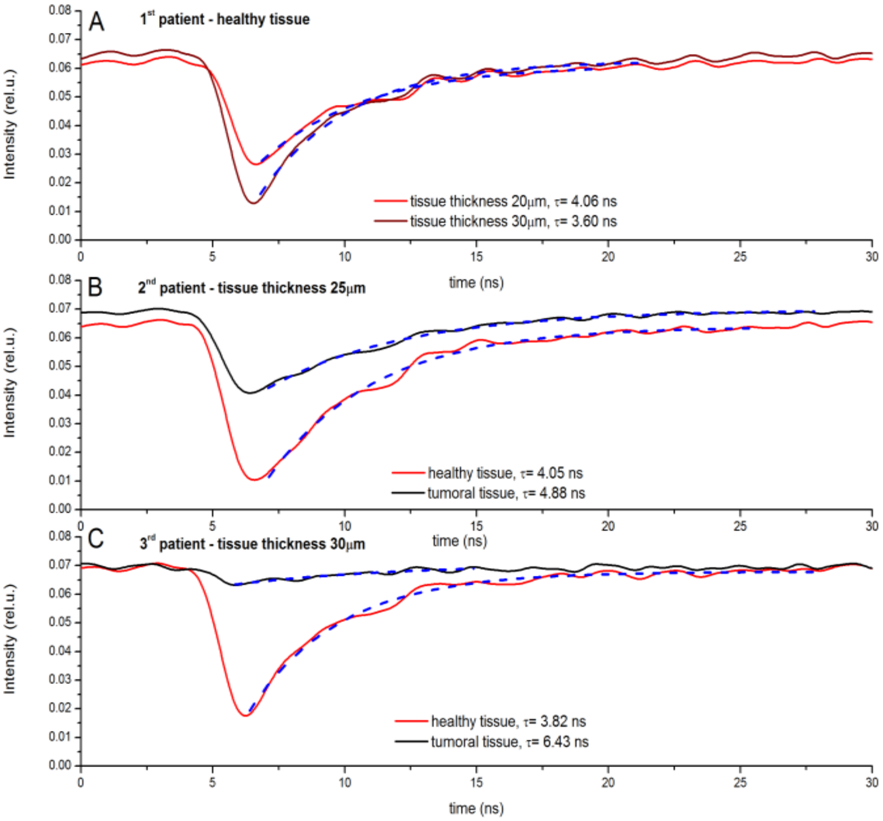
The results indicate that values of LIAF's parameters (wavelength, intensity, area, I/FWHM) are helpful and complementary diagnostic tools in detection of laryngeal carcinoma. These variations are due to the different concentrations and distribution of fluorophores in the samples.

Table 1. Parameters extracted from LIAF spectra for the 2nd and 3rd patient healthy and tumoral tissues (rel. u. are different from one column to the other; the same values of rel.u. are used for different patients)

Patient	Tissue	λ_{peak} (nm)	I_{max} (rel. u.)	FWHM (nm)	Area (nm x rel.u.)	I/ FWHM
2nd	Healthy	457	2.29x10^4	107.48	2.58x10^6	212.6
	Tumoral	457	2x10^4	98.5	2.13x10^6	202.5
3rd	Healthy	458	1.92x10^4	101.69	2.07x10^6	188.5
	Tumoral	449	5.56x10^4	114.6	6.87x10^6	48.56

Regarding LIAF's life-time (Figure 6), performed measurements show that the life-time of the healthy tissue decreases with thickness increasing, both for first patient case (Figure 6A) and for the second and third patients (Figures 6B and C, respectively). In Figure 6A, the life-time value decreases from 4.06 ns for the tissue of 20 µm thickness to 3.6 ns for that of 30 µm thickness, both values being obtained by averaging 4 samplings.

Figure 6. LIAF's life-time. A) 1st patient, healthy tissue at two thickness, 20 and 30 µm; B) 2nd patient, healthy and tumoral tissues at 25 µm tissue thickness; C) 3rd patient, healthy and tumoral tissues at 30 µm tissue thickness; blue dash line indicates the exponential decay fit function whose time constant τ represents life-time of the analyzed process.



It is to mention that the life-time values of healthy tissue for second and third patients are similar with those for the first patient considered for the same tissue thickness. For both patients exhibiting developed malignant tumor, the life-time values were higher for the cancerous tissues than the healthy samples (4.88 vs 4.05 ns for second patient; 6.43 vs 3.82 ns for third patient) as we see in Figures 6B and C.

DISCUSSION

The prognosis for patients with laryngeal cancer is significantly better with early detection of malignant lesions. Therefore, otolaryngologists look for supplementary techniques, as laser-induced autofluorescence, which may improve accuracy of real time cancer detection.

Malzahn et al. [9] have demonstrated high sensitivity of autofluorescence endoscopy in the diagnosis of early laryngeal cancer compared with light endoscopy alone. In the study of Zargi et al. [10] the sensitivity and specificity of described method were 86.9% and 82.8%.

The aim of the presented study was to analyze the applicability of laser-induced autofluorescence measurements to the differentiation of the changes in the cancerous and healthy tissue of the larynx. For the measurements, it was used a laser diode emitting pulses of picosecond duration and λ = 375 nm. The chosen wavelength was found to excite the endogenous fluorophores: tyrosine (max. emission at 310 nm), tryptophan (max. emission at 340 nm), oxidized form of nicotinamide adenine dinucleotide (NAD+) (max. emission at 460 nm), the collagen cross-links (max. emission at 420–460 nm), the reduced form of nicotinamide adenine dinucleotide (NADH) (max. emission at 460nm), and the oxidized form of flavin adenine dinucleotide (FAD) (max. emission at 520 nm) [11]. The levels of the mentioned fluorophores, especially NADH and FAD, provide a strong emission signal and are significantly altered in cancerous cells, enabling the differentiation of the healthy and neoplastic tissues by autofluorescence measurements [12, 13, 14].

In both cases of the study, the LIAF's intensities of the cancerous tissue samples are lower in comparison with the adjacent healthy tissue samples. These results are in accordance with other studies where the decrease of intensity may be a consequence of reduced concentration of oxidized flavoproteins, the breakdown of collagen cross-links, the thickening of the cancerous tissue or the blood absorption (neovascularisation, inflammation)[15,16]. Neoplastic cells infiltrating submucosa express matrix metalloproteinases activity, which participate in breaking collagen cross-links [17].

We also observed in both cases that the area of LIAF for cancerous tissue is smaller than healthy tissue, the value of the ratio Intensity/ Full width at half maximum (I/FWHM) decreases in cancerous tissue sample and maximum spectrum for tumor sample is shifted towards blue. As for LIAF's life-time, in both cases the values were higher for cancerous tissues than healthy samples. Measurement of these parameters gives to our study originality, as well as the experimental setup.

Our results indicate that LIAF's parameters values (intensity, area, I/FWHM, life-time) are potentially a very helpful, complementary, diagnostic tool in detection of laryngeal carcinoma. The clinical prospective research on a great number of patients should be performed to establish utility of these measurements in everyday practice.

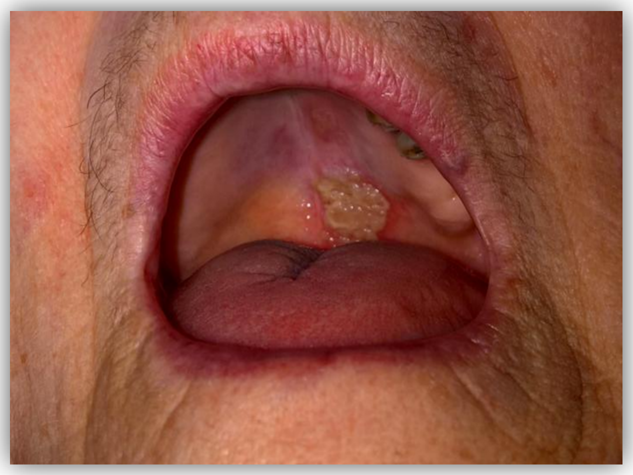
Mucous herpes zoster in elderly

Daniel O. Costache[1], Ionel Ţoropoc[1], Ciprian Jurcuţ[1], Cătălina Diaconu[1], Laura Voicu[1], Raluca S. Costache[1,2]



78 years old female is admitted in hospital for low back pain with moderate dysfunction and headache, secondary associated with vesicular/ pustular and ulcerative lesions in the mouth (image).

The patient has a cardiovascular medical history with severe arterial hypertension, grade 1 atrio-ventricular block, paroxistic atrial fibrillation, mitral and tricuspidian regurgitation, congestive heart failure NYHA II and chronic renal disease stage IIIB.

Biologic findings shows slight normochrome anemia, WBC was within normal range and no signs of inflammation. Ag Hbs, Ac anti HVC, HIV were negative. Beta haemolitic streptococcus and staphylococcus aureus were absent.

The imagistic standard evaluation (ultrasound) has normal findings.

Patient developed an erythematous patch on the soft palate, with pustules and ulcerations, slightly painful, and some vesicles on the left side of the tongue. No lymphadenopathy was present. It was interpreted as mucous herpes zoster and Acyclovir treatment, 4 grams daily for 7 days was initiated. From the 5th day the subjective symptoms disappeared and local manifestations tend to diminish.

Herpes zoster is the result of VZV reactivation and its spread from a single ganglion to the neural tissue of the affected segment and the corresponding cutaneous dermatome. When the virus is located and multiplies in the geniculate ganglion, facial, aural, and oral lesions of herpes zoster may emerge. Reactivation in the geniculate ganglion can lead to facial nerve (VII) paralysis (because sensory and motor nerves conjoin in nerve VII). VZV and HSV account for the majority of cases of Bell palsy (idiopathic facial paralysis). Our case was not one of those.

Under treatment, evolution was favorable, and 1 month after stopping treatment there were no residual symptoms.

Syrian war shrapnel injury: cubital nerve defect grafting during humanitarian surgical mission. Clinical case presentation

Argentina Vidrașcu[1], Paul Polihovici[2]

Abstract: *Background and aim of this clinical case presentation is to reveal the importance of early nerve injury diagnosis and surgical treatment in war wounded patients.*
Methods. The author treated patients in Amman Charity Hospital were among different plastic surgery cases where limb nerve injuries with nerve grafting indication. The presented case was treated with autologus sural nerve graft.
Results were evaluated at 3 months after the surgery and revealed detectable nerve conductibility at the Electromiography test.
In conclusion, in cases with delayed nerve repair surgical treatment in war wounded patients, the vascularised nerve graft can be a better solution for nerve defect surgical treatment.

Keywords: *NERVE injury, axonotmesis, war wounded patient, sural nerve graft, microsurgery, ulnar claw*.

CASE REPORT

Acute and chronic war wounded Syrian refugees from Zaatari camp and the Syrian battlefields are directly admitted in Amman Al Maqqased Charity Hospital every day.

Among patients treated by the author during November 2015 Humanitarian Mission was a left cubital nerve defect due to a bomb explosion injury.

Peripheral Nerve injury described by Sunderland classification can be: neuropraxia as the lowest degree of nerve injury in which is affected only the nerve conduction and no disruption is done. The second degree is axonotmesis where the axon is damaged but the surrounding tissue remains healthy (1). The most severe form of nerve lesion is neurotmesis where both the surrounding tissue and the axones are disrupted (2).

Patient's surgical and medical history

Female patient, 42 years injured 8 month prior to surgery. Immediately after the explosion the patient received first aid surgical assistance: wound cleaning and direct closure.

The patient felt on the first postoperative day that she completely lost the tactile sense on 4th and 5th fingers on her injured left hand.

---

[1] Constantin Papilian Military Emergency Hospital Cluj - Napoca
[2] Iuliu Hatieganu University of Medicine and Pharmacy Cluj Napoca

During the healing process, the wound infection and sutures opening occurred and the patient was treated with antibiotics and wound dressings until the wound has completely closed.

Two months after the injury she was examined and diagnosed with post traumatic cubital nerve injury.

Clinical and paraclinical information

The patient presents left cubital nerve chronic palsy with "ulnar claw" appearance and extensive (12 cm) longitudinal scar on the palmar aspect of the forearm (Figure 1). The metacarpophalangeal joints of the 4th and 5th fingers are extended and the interphalangeal joints of the same fingers are fixed in extension.

Figure 1: Left hand war injury with antebrahial wound and hypothenar region muscular atrophy.

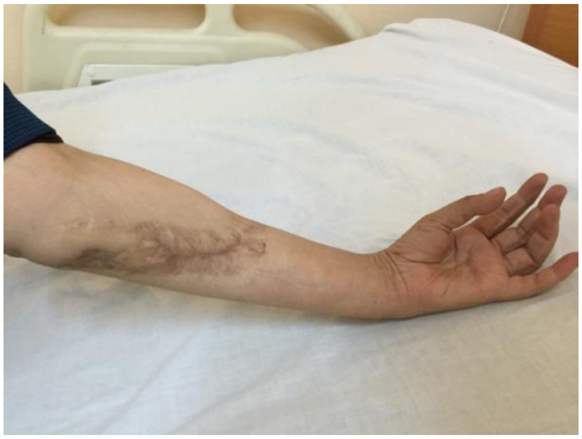

Figure 2: Ulnar claw hand aspect with insufficient flexion of the 4th and 5th finger's interfalangial joints.

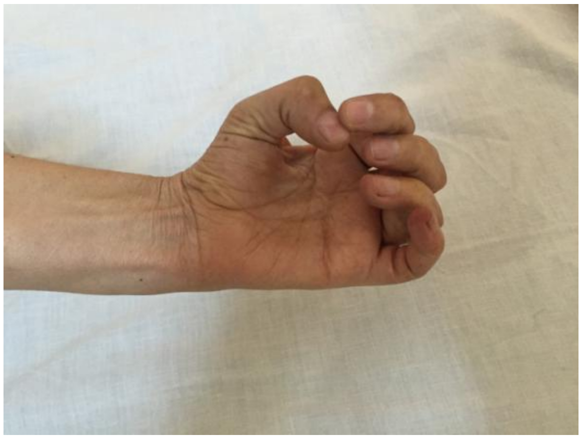
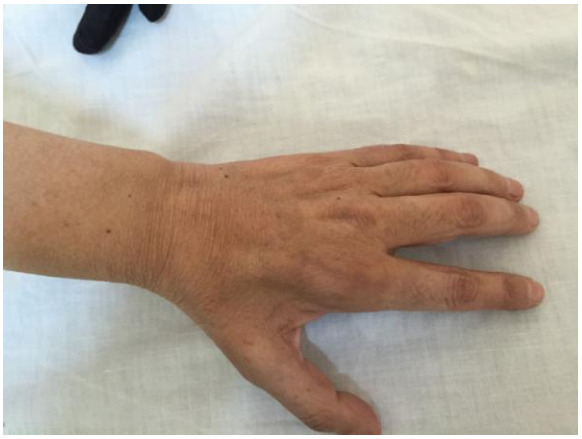


The claw is most obvious when the patient is asked to flex all fingers: the 1st and 3rd digits are flexing due to intact medial nerve innervation and the 4th and 5th ones are remaining extended because of high cubital nerve injury (Figure 2).

The final diagnosis is clarified by dorsal and hypothenar regions denervation and atrophy and by Electromiography testing which reveals the left ulnar transmission is completely disrupted at the scar site (Figure 3).

Figure 3: The dorsal aspect at the cubital denervated hand with muscle atrophy.



The nerve injury is grade 5 according to Sunderland's system.

Surgical method

Clinical practice and research on nerve injury treatment indicates that the primary surgical repair during the first week is required. If the nerve is disrupted on more than 2 cm length the sural nerve graft must be done.

The surgery was performed under general anesthesia using an interfascicular microsurgical nerve suture technique.

The partial scar excision was done and fibrosis was devided.
Cubital nerve was found being disrupted on 10 cm length at the medial 1/3 of the forearm. After debridement and neurolisis due to myeline degenerative process, the gap real size was 14 cm long (Figure 4).

The autogenous sural nerve grafting was decided to be done.

The right 18 cm long sural nerve graft was harvested and a cable graft designed to bridge the gap (Figure 5).

Figure 4: Cubital proximal and distal nerve stump after surgical debridement.

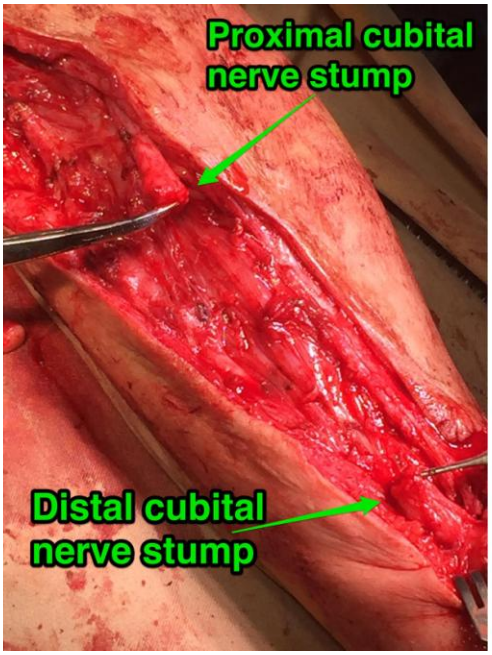


Figure 5: Right Sural nerve graft harvested.

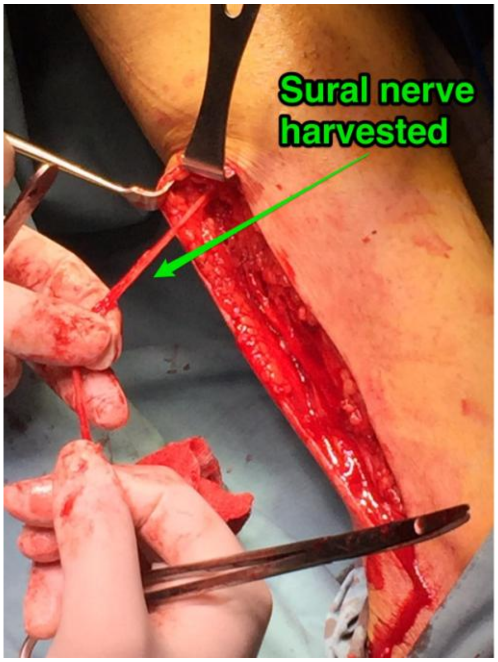


The microsurgical sutures were done at the both nerve ends to achieve nerve connections with separate nonabsorbable 7-0 sutures (Figure 6).

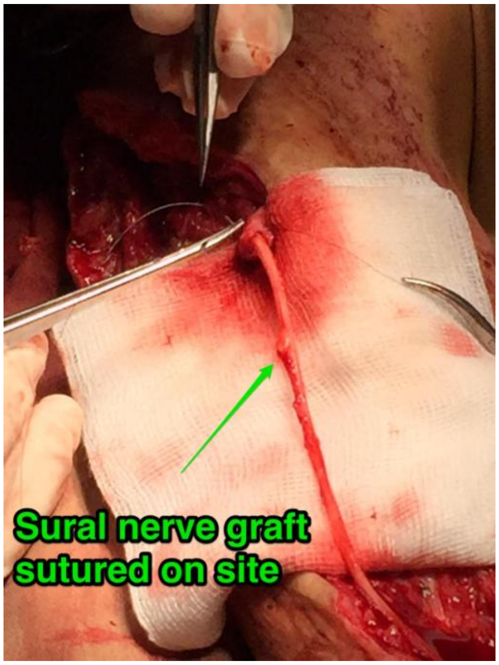
Skin suture and hand splinting was done.

The patient's evolution was favorable under antibiotic therapy for 7 days with no wound closure complications.

Results

After 3 months of kinetotherapy and electrotherapy the nerve conductibility was evaluated as being detectable at the lowest level by Electromiography test. No sensitivity or lightning in the 4th and 5th fingers was detected.

Figure 6: Sural nerve graft sutured on site.



Continued hand therapy rehabilitation is indicated and, 6 and 12 months postoperative evaluation by Electromiography and two point discrimination tests are mandatory at each following checkup.

DISCUSSION AND CONCLUSION

The nerve injury repair should undergo in most of the cases on the emergency surgical treatment basis.

In neurotmesis cases the immediate surgical repair attitude (one week) is the preferred approach for nerve defect treatment in order to obtain a high sensitive and motor functions recovery rate (3).

In chronic palsy (lasting > 3-4 months) associated with muscle weakness, atrophy, surgical outcome is less certain. The duration of palsy and muscle weakness are key factors influencing the prognosis (4).

No conservative treatment can be done in such cases just bridging segmental nerve defect with autogenous nerve graft or decellularized nerve allograft and nerve tubulisation in repairing defects less than 5 cm (5).

In present case the grafting was done 8 months after surgery – this may lead to a less motor recovery but sensitive recovery still can be a good one 6 months after continuous hand rehabilitation(6-8). This demonstrates that 3 months after surgery the cubital nerve conduct was detected even at the lowest level.

In war areas where patients cannot seek specialized medical attention immediate after the injury and their nerve palsy is diagnosed later on, a vascularized nerve grafting should be considered as a clinical alternative for nerve reconstruction if sensitive sense it is not improved after nerve grafting.

Further research comparing late nerve grafting versus vascularized nerve grafting must be done.

The not so good and the not so bad

Silviu V. Dumitrescu[1]

Today's question: How good is the good cholesterol?

Since before med school we knew that is a bad cholesterol and a good one. And like old days vigilantes we fight the bad one and support the good. But, like the characters in the novels, the bad one seems to have a bright side and the good one has dark secrets.

First let's talk about the LDL. It's involvement in atherosclerosis it's a fact and it's a silent killer. The cardiologists are fighting it since 1987 when the introduction of lovastatin in ischemic cardiac disease was a real breakthrough. But what the neurologists have to say? After the initial enthusiasm was tempered they started to ask: our patients have a LDL cholesterol level way below 70 mg/dl. They are safe. But they look dumber. Why? The statin lead to a mental decline or the low LDL level is to blame? In my opinion is the LDL level. I noticed that in several of my patients with very low LDL levels: they develop very fast dementia symptoms that regress dramatically when their LDL levels rise above 70 mg/ml. Is it a coincidence? Maybe. But what if the bad has good side?

Figure 1: The good and the bad cholesterol [5].

Now let's talk about the sheriff, HDL cholesterol. The one that protect us in the front of vascular aggressors. We know that the bigger is the better and we are very sad when our patient have low levels of it. But 500 years ago we knew that the earth is flat, so what is the truth?

Recently 4 Big Pharma firms developed a new class of lowering cholesterol drugs – Cholesteryl Ester Transfer Protein Inhibitors (CETPi) that were announced to be the new milestone in the treatment of dyslipidemia. Preliminary studies showed a spectacular HDL levels rise.

First to go first to fall – torcetrapib – shortly the mortality increased from an unknown cause.

Next dalcetrapib and evacetrapib – HDL levels reached the top. Well tolerated, few side effects, no increased mortality.

Then the bomb dropped: the studies were shutdown prematurely. Why? Headmaster of the late ACCELERATE study, Steve Nissen declared for Forbes magazine that “the drug didn’t work". I don't think that was the accurate response. In my opinion the drug worked because patients achieved incredible high HDL levels. The problem was that despite these very high HDL levels the cardiovascular events were not different from the placebo group. So I would say that drug proved to be effective in what it was made to do but high HDL levels were useless.

---

[1] Acad. St. Milcu Medical Diagnostic and Treatment Outpatient Centre, Bucharest

Here comes the question: is the HDL as protective as we used to believe or just handsome good-for-nothing cholesterol as suggested by those studies?

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related "mini-series" of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors'

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research

must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

EDITORIAL

About clinical medicine: Is there still such a thing?

Dan Mischianu

Gral (R) Prof DAN MISCHIANU
Chief of Urology Clinic, Carol Davila Central Emergency Military Hospital
Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

The other day, a distinguished and well known specialist radiologist from Bucharest shared with me two absolutely surprising things.

First: not long ago, an experienced internal medicine physician addressed expressly with the request to radiologicaly examines a patient with, in his opinion "acute pulmonary edema"! The radiologist told me that the “acute pulmonary edema” was actually a "spontaneous pneumothorax" probably due to rupture of emphysematous bubbles. The thoracic surgeon solved the so-called "acute pulmonary edema" actually "spontaneous pneumothorax" by specific means...

The second issue told by the radiologist: I can sit at home in front of my laptop and receive scanned images of patients from different locations (clinics, private hospitals) in the country (Bacau, Constanta, Baia Mare and so on), then I say my opinion and the fee is in my account!

I asked him slightly amazed: Yeah, well, but do you not feel the need to learn more about that patient? Did you forget what we learned in medical and surgical semiology that 80% of the diagnosis belongs to anamnesis? Do you not need to palpate, to auscultate or to listen to what the patient tells you...? Have you not learned anything from the mistake of the internist who "din not use a stethoscope" to find, in fact, that he had no vesicular murmur? My friend did not answer…

In fact what do I want to say in this editorial?

First I want to say that our guild lives in a perfect confusion: notions or concepts of "evidence-based medicine (EBM)", "alternative medicine", "noninvasive" medicine, "medicine x, y, z" and many others can only leave room for speculation. Medicine, as illustrated, has always been great at removing great speculations because of phantasmagoric individuals like Paracelsus or Mesmer...

Secondly, in Adevarul newspaper from 02/19/2016, Theodora Şopaltă, a journalist, was writing sententiously: "There are five types of doctors. Which one do you prefer?" The first type, in the opinion of the author is “The clever" (30% of respondents voted for him), then comes "The Digital doctor” (which probably specify diagnosis texting his phone! preferred by 8% of respondents), then comes “The Wise man" who do not talk to patients about their illness but gives them an accurate diagnosis. Go figure it! In fourth position lies "The Idealist", preferred by 24% of patients, said to be a younger version of "intelligence" and the ending is marked by "Only You", a "pragmatic option of alternative medicine."

Thirdly, I say that doctors may be labeled as "made and born" to practice this noble profession, for which are made after the Hippocratic precepts and not by strange and awkward ideas, good and honest doctors with knowledge of human nature, easily grasping which in this profession gives you a disadvantage and "good for nothing doctors" who easily realize that there is no place for them amongst us and change their job to managers, adventurers, free – thinkers and so on.

To end this Editorial I conclude by saying that a good and honest clinician is the one that accepts and applies the perennial teachings of Hippocrates of Cos and takes into account the lessons of the Great surgeon and Great clinician, Professor Dr. Ion Juvara:

"Whatever novelty and complexity of laboratory methods of investigation, clinical retains its entire value, observation of man by man offering truths that never grow old”

I believe and hope that there still is the so-called "Clinical medicine"!

Article received on March 2, 2016 and accepted for publishing on May 21, 2016.

REVIEW ARTICLE

MRI fusion biopsy vs transrectal ultrasound guided biopsy – A literature review

Constantin A. Rădulescu[1], Mihai F. Rădulescu[2], Gina A. Ciucă[1], Dan Mischianu[1,3]

Abstract: *Introduction: Current diagnosis of prostate cancer is based on transrectal ultrasound guided random biopsies. These procedures alongside with the discovery of PSA lead to a tremendous improvement of prostate cancer diagnosis rate in the last decades. Random ultrasound guided biopsy has its minuses and several attempts were made to improve the detection rate of the disease. MRI-US fusion targeted biopsies is one of them.*

Aim: This paper is a literature review of several important European studies and tries to draw a conclusion for the usefulness of MRI-US image fusion prostate biopsy in improving prostate cancer detection

Material and methods: We have analyzed 5 papers published since 2013 which compare random ultrasound biopsies with MRI-US fusion. The analyzed parameters were clinical significant cancer detected as described by the study and any cancer detected

Results: All 5 papers show superiority in cancer detection rates for both clinically significant and any cancer.

Conclusions: MRI-US is a useful tool for improving detection rate of clinically significant prostate cancer.

INTRODUCTION

Prostate cancer is a serious public health matter, being the first cancer in men in terms of incidence and the second cause of cancer death in the U.S. Cancer, in general is taught to surpass in the following year cardiovascular diseases as the leading cause of mortality. Prostate cancer, in particular is becoming more and more important due population aging. [1]

While throughout the history prostate cancer was poorly understood, with few cases recorded due to the low life expectancy, during the XXth century groundbreaking discoveries were made in understanding, diagnosing and treating the disease.

Early diagnosis methods included open transperineal biopsies, blind transperineal needle biopsy and finger guided transrectal biopsy. First attempts to use transrectal ultrasound for prostate imaging were made by Takahasi and Ouchi in 1963 but they obtained poor images [2]. Watanabe in 1968 performed first clinical useful TRUS. In 1989 Hodge and al. started the modern era of standard sextant

transrectal ultrasound guided needle biopsy. Stamey developed a technique which consisted in performing a biopsy without knowing the tumor location within the prostate. Stamey's method was a major advance over older methods in which biopsy needles were guided only by the examining finger.(2) During the late 1990's and early 2000's standard protocol was modified introducing extended and saturation biopsies. Nowadays it is estimated that several million biopsies are performed each year around the globe.

Ultrasound guided transrectal biopsies have 2 major disadvantages: detection of focal carcinomas with little or no clinical significance on one side and the important percentage of falsely negative biopsy cores.

MRI was invented in 1971 by Paul C. Lauterbur for which he was granted Nobel Prize for Medicine in 2003. MRI evolved as being the most important tool for prostate cancer staging, especially if performed in a multiparametric manner.

Prostate biopsies can be performed directly under IRM guidance or images may fused either in a cognitive manner, a method dependent on operator's experience, or MRI-US image fusion may be used. When using US-MRI fusion, standard transrectal ultrasound is performed and software is utilized to fuse the ultrasound images, at the time of the examination, with IRM images that were obtained before.

3D images of the prostate are obtained [3]. Fusion devices use a variety of technologies to perform image fusion. There are devices which perform robotic tracking via a mechanical arm with built-in encoders with commercial products: Artemis and BioJet. Electromagnetic tracking is used by the following UroNav and Hi-RVS. A 3D US probe is used for tracking and fusing images by Urostation. [4]

MATERIALS AND METHODS

We have analyzed 5 major studies which were performed since 2012 in terms of number of subjects, medium PSA level, overall cancer detection and clinically significant cancer detection rates. All 5 studies analyzed were paired cohort studies which compared transrectal standard biopsy with MRI-US fusion biopsy. The population analyzed was heterogenous. The only thing that was common to all patients was high PSA levels. One study, (Sonn GA et al, 2014)[5] had only patients with prior negative biopsy while the other 4 studies had mixed patients with or without prior negative biopsies. The percentage between patient with and without negative biopsies varied.

The number of patients varied between 30 (Fiard et al, 2013) [6] and 347 (Kuru et al, 2013) [7] with a total of 677 patients. Medium PSA recorded in each study varied between 6.3 ng/ml (Fiard et al, 2013) and 9.85 ng/ml (Kuru et al, 2013).

Clinically significant prostate cancer was defined by each study. Sonn et al defined clinical significance as Cancer positive cores with length 4 mm or more or Gleason 3+4.

Kuru et al used the NCCN (National Comprehensive Cancer Network) criteria. Fiard et al and Rud[9] et al considered clinical significance when Gleason 7 (3+4) or higher was recorded on biopsy cores while Rastinehad et al[8] used Epstein criteria for clinical insignificant tumors: clinical stage < T1c; PSA density < 0.15 ng/ml; fewer than 3 positive cores and less than 50% cancer on positive cores.

Clinically significant disease, defined as above, was diagnosed by means of transrectal ultrasound guided biopsy in 4.8% (Rud et al,2012) to 38% cases (Kuru et al, 2013) with a mean value of 25.26% and by means of MRI-US fusion biopsy in 21.7% (Son et al, 2014) to 50% cases (Rud et al, 2012) with a mean value of 40,76%.

The difference in diagnosing clinically significant disease varied between 7% to 41.4%. MRI-US fusion biopsy was more accurate in diagnosing clinically significant prostate cancer compared to US transrectal biopsy with an overall advance of 17.36%.

When analyzing all types of cancer both clinically significant and insignificant 4 out 5 studies showed superiority of MRI-US fusion biopsy ranging from 0.2% to 53.2%. Sonn GA et al reported 27.5% for

TRUS biopsy vs 23.7 % for MRI-US fusion. This difference in favor of TRUS is probably linked to the study design as it is the only cited study that enrolled only patients that had undergone a prior negative TRUS biopsy.

Table1: Prostate cancer both clinically significant and any cancer

Paper	Clinically significant TRUS	Clinically significant MRI-US fusion	Any cancer TRUS	Any cancer MRI-US fusion
Sonn GA et al	14,7%	21,7%	27,5%	23,7%
Kuru et al	41,1%	50,4%	50,4%	50,6%
Fiard et al	33,3%	50%	43%	55%
Rastinehad et al	32,4%	44,8%	48,6%	50,5%
Rud et al	4,8%	46,2%	14,3%	67,5%
Medium values	25,26%	42,62%	36,76%	49,46%

DISCUSSIONS

All studies show superiority for detecting clinically significant disease with a smaller number of biopsy cores for MRI-US fusion biopsy and all but one showed overall superiority in detection of prostate cancer.

The disadvantages of this review are the fact that there isn’t a standardized definition of clinical significance, the lack of homogeneity of the analyzed population, the fact that some studies have enrolled both patients with prior biopsies and patients without biopsies, and the lack of standardized protocol for MRI-US fusion biopsy as there is a standard protocol for TRUS biopsy.

CONCLUSIONS

MRI-US fusion biopsy has proven to be more accurate in detecting clinically significant cancers but is still long way from becoming a standard procedure because of the complex technique required, the financial burden caused by the need of a prior MRI.

MRI is capable of accurately diagnosing prostate cancer, in assessing its extension, its aggressiveness. MRI is also a useful tool for following patients with prior diagnosis of prostate cancer and probably, in the future it will be the major tool for focal therapy of the tumor.

Transrectal ultrasonography still holds the crown for prostate cancer detection and will certainly remain the most used guidance technique for prostatic biopsies for long time with good results in the general population. Patients with negative biopsies and who experience a continuing rise in PSA levels, patients at risk when talking of hereditary antecedents of prostate cancer and some other risk categories may and will certainly benefit from the development of the MRI fusion technique.

REVIEW ARTICLE

Article received on March 5, 2016 and accepted for publishing on May 16, 2016.

The role of contrast-enhanced ultrasound in risk assessment of carotid atheroma

Silviu Stanciu[1], Cristina Enciu[1], Ioana Răduţă[1], Dan Stoicescu[1], Adrian Anghel[1], Daniela Anghel[1], B. Olan[1], Lucian Ciobîcă[1]

Abstract: *Background and objective: Contrast-enhanced ultrasound, used to assess atherosclerotic carotid plaques, improves visualization of vessel wall irregularities and depicts intraplaque neovascularization. This article illustrates the use of contrast-enhanced ultrasound in the risk assessment of carotid atherosclerotic lesions, especially in challenging plaques evaluation.*

Materials and methods: For 23 patients with difficult duplex ultrasound examination due to carotid tortuosity or calcifications we assessed plaque morphology (contour, echogenicity and stenosis degree) using contrast substance (Sonovue, Braco) with dedicated vascular low mechanical index CPC software.

Conclusion: Contrast-enhanced ultrasound is a new, noninvasive, and safe procedure for imaging carotid atherosclerotic lesions. It is a valuable tool for evaluating the vulnerable plaque at risk for rupture and for the diagnostic of the development and severity of systemic atherosclerotic disease.

INTRODUCTION

Carotid atheromatous pathology is responsible for almost 1/3 of strokes through 3 basic mechanisms: atherothrombosis, distal embolism from plaque origin and hemodynamic effect in the case of significant, severe stenosis (1).

Carotid ultrasound technique remains the benchmark for the assessment of carotid-vertebral arterial axis, mainly regarding the presence of obstructive atherosclerotic plaques with a proper evaluation of morphology and stenosis degree, by combining the two methods of examination: Duplex mode-B mode and Doppler mode (Color and Spectral).

Numerous studies have shown the beneficial role of endarterectomy or stenting in stroke rate reduction, in symptomatic and asymptomatic patients with significant stenosis of over 70%, but there is no clear attitude regarding the therapeutic approach of asymptomatic patients with a lower degree of stenosis. In these patients, in whom stenosis has no cerebral hemodynamic effect, several studies emphasize on plaque morphology, by identifying unstable plaques which would play an important role in the development of symptoms (2).

Often, we encounter in daily clinical practice cases where carotid axe imaging becomes challenging due to intense calcifications in the carotid bulb and origin, due to the presence of carotid tortuosity or because of the impossibility to distinguish between

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest

preoclusive (over 90%) stenosis and complete occlusion, which would change the therapeutic approach (3,4).

To overcome these limitations and better characterize unstable plaques, by highlighting the intraplaque neoangiogenesis (5), recently a new imaging technique has been developed using contrast substance, which has the advantage of strictly vascular and plaque and wall vascularization distribution.

MATERIALS AND METHODS

During the last year, for 23 patients with difficult duplex ultrasound exams due to carotid tortuosity or calcifications we performed a contrast enhanced evaluation in order to assess plaque vascularization and stenosis degree.

In consequence, the protocol for plaque morphology description (contour, echogenicity and stenosis degree) consists in 1 ml bolus of contrast substance (Sonovue, Braco) administered through a catheter in the right arm, followed by 10 ml bolus of saline with the acquisition of 6 seconds clips during 4-5 minutes, maneuver which can be repeated to achieve the objectives of the study.

In our department we currently use dedicated vascular CPC software with low mechanical index, integrated into a SIEMENS Sequoia 512 CV system.

In each case we observed the contrast substance plaque penetration, carefully identifying and assessing intraplaque vascular pattern.

Detecting intraplaque angiogenesis

In the majority of patients (68%) with echogenic plaques and no significant stenosis (lower than 70%) intraplaque vascularization has been found, with outside to inside filling pattern, data similar to literature findings (see images).

The existence of this new angiogenesis vessels, mainly situated at the base of atheromatosic plaques, can be considered a risk zone for possible plaque rupture, resulting in major stroke.

Figure 1: Transverse cross section right after left CCA bifurcation, 30 seconds after contrast substance has been administered. Note the lack of opacification of left ICA due to the presence of atheromatous plaque responsible for a 60-70% stenosis.

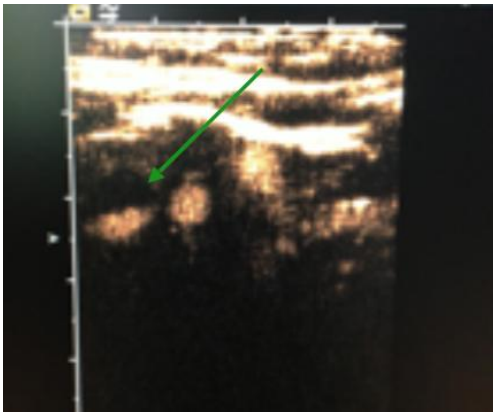

Figure 2: Longitudinal section 40 sec after the injection allowing plaque visualization at the origin of the left internal carotid artery with contrast enhancement at the base (arrow)

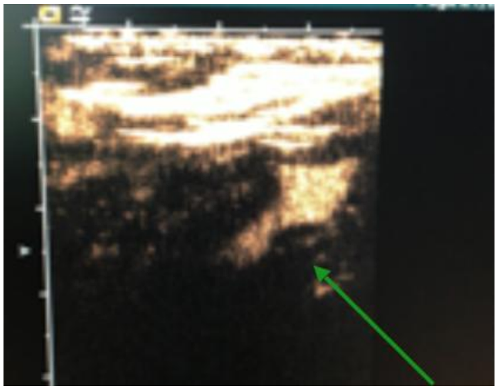

Figure 3: Same plaque from figure 2 at 60 seconds after injection

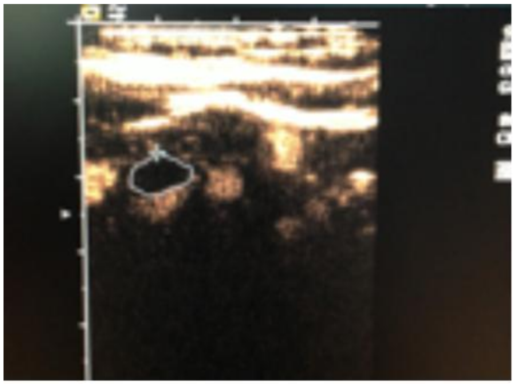

Figure 4: Contrast enhancements at 70 seconds with a filling patter from the outside to inside

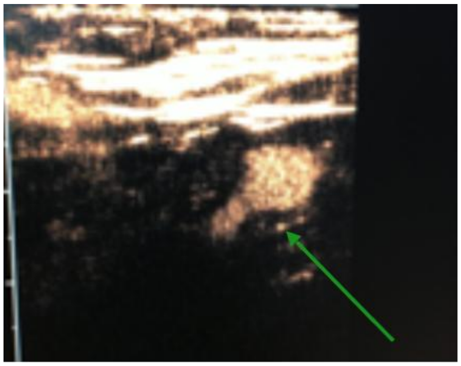

In consequence, identifying intraplaque neovascularization in patients with no significant carotid stenosis can be considered a noteworthy additional argument when considering an interventional procedure (stenting or endarterectomy) for stroke prevention.

DISCUSSION AND CONCLUSIONS

The concept of unstable or vulnerable plaque, similar to that seen in coronary pathology, is based upon identifying dangerous plaques with immediate stroke like complications, with acute inflammation and angiogenesis (which precede and cause plaque rupture or ulceration), that can't always be detected through conventional duplex ultrasound.

Carotid ultrasound remains the leading non-invasive exploration regarding pre-op/pre-interventional or post-op/post interventional functional and anatomic evaluation. Contrast-enhanced ultrasound studies, bring additional information regarding carotid stenosis quantification in difficult evaluation situations (calcified plaques or difficult to explore vascular tortuosity) but especially brings functional information regarding intraplaque vascularization, thus identifying unstable and high stroke risk plaques allowing an appropriate therapeutic approach.

The importance of life quality questionnaire in patients with prostate cancer, pre- and post-radical prostatectomy

Gina A. Ciucă[1,2], Ovidiu Bratu[1,2], Dan Spînu[1,2], Marius Dinu[1], Cătălin Farcaș[1,2], Constantin A. Rădulescu[1], Robert Popescu[1], Dragoș Marcu[1], Dan Mischianu[1,2], Petru Armean[2,3]

Abstract: *This study analyzes the satisfaction of the patients with radical prostatectomy according to the signs and symptoms included in the EORTC QLQ – C30 and EORTC QLQ – PR25 questionnaires, including their relation with the health state that influences the pre and postoperative life quality.*

Fifty patients with prostate cancer in a localized stage were studied and analyzed in a prospective manner and for a period of 12 months, before and 6 months after the radical prostatectomy. In choosing the patients, the common denominator was the use of the same postoperative plan and the lack of postoperative complications, as well as the lack of chronic diseases.

Erectile dysfunction, urine incontinence were quite frequent after radical prostatectomy, while the urinary obstruction and the weak urinary stream were less frequent. In this regard, people noticed a significant decrease of life quality.

Although the study addressed a small group of patients, the results are similar to those belonging to other clinical studies. Even if the aspect of life quality is more rarely taken into account, the questionnaires regarding the life quality are specific, useful and quite cheap in evaluating different therapies.

Keywords: *life quality, prostate cancer, questionnaire*

INTRODUCTION

Prostate cancer represents a disease with increased prevalence, being the second cause of death in U.S.A, on the first place being the lung cancer. However, the prostate cancer shows optimistic survival rates, the rate of the deaths caused by the prostate cancer decreased in the U.S.A, from the beginning of 2007 with 3.2%[4]. This fact led to the appearance of a model of patients with prostate cancer, patients for whom the quality of life is important, as well as the impact of the disease on this.[5].

For those who study the clinical problem, the aim of evaluating life at the patients with prostate cancer consists in evaluating the effects of the treatment on the symptoms and in identifying the negative impact of the disease on the life of the patient.

The quality of life is a concept that has started to be studied and taken into account in 1946 when in the

[3] Th. Burghele Urology Hospital, Bucharest

Preamble of the Constitution of World Health Organization, health was defined as it follows: ,,*Health is the state of complete physical, mental and social wellbeing that does not reduce at the absence of a disease or of an infirmity"[1,2].*

Smith and his contributors consider the notions of life quality and the health as being two defined concepts, the life quality being related even more to the mental health, while the state of health hints at the physical function [3].

Meaning ,,a holistic auto evaluation of satisfactions regarding the individual", the life quality is a much – disputed concept, multidimensional that, though seems quite easy to understand it, is difficult to be defined.

In a more restrictive meaning is used the term of life quality regarding health ,,health related quality of life" (HRQL),to define the influence of health and nursing on the life quality, being influenced by numerous factors like: financial state, habitat, the work place, the spirituality, the social support and the health of the individual [2].

The evaluation of the aspect regarding the quality of life in patients with prostate cancer is done at a large scale in the clinical studies, but it must be underlined the importance of using these evaluation methods in clinical practice [1].

The questionnaire, a descriptive instrument, is the one through which the evaluation is done in a subjective manner a wide range of the disease effects that are, later, resumed into a final score.

The evaluating instruments of the quality of life come to complete the other methods of investigation of the patient with prostate cancer, for this very reason it would be opportune to facilitate the use of these by the people who study clinical problems, the subsequent therapeutic conduct being able to improve the quality of life for these patients.

The most used questionnaires in the clinical practice in evaluating the patients with prostate cancer are the following: EORTC QLQ-PR25 and EORTC C-30 questionnaires.

The quality of life as a medical concept explains the effects of diseases and those of the therapy on the stage of comfort for the patient that is the subject of evaluation with the help of the questionnaires.

The questionnaires can be completed by the medical personnel, the patient being asked the questions after having read and signed the informed consent or directly by the patient.

The first method has the advantage that the doctor can explain the patient the questions more accurately, diminishing the misunderstandings, but the result cannot have a maximum accuracy as not all the patients can be very honest while facing other persons.

MATERIAL AND METHOD

Fifty patients with prostate cancer in a localized stage were studied prospectively for 12 months, before and at 6 months after the radical prostatectomy between January 2015 – December 2015, at the Urology Clinic of the Carol Davila Central Military Hospital.

In choosing the patients, the common denominator was the use of the same postoperative plan and the lack of postoperative complications, as well as the lack of chronic diseases.

The average age of the patients included in study was of 65.

The patients were asked to fill in the EORTC C-30 and EORTC QLQ-PR25 in Romanian language, after having read and signed the informed consent.

The characteristics of the group of patients were recorded and processed in a SPSS database (version 22 – Chicago k, USA).

The EORTEC C – 30 questionnaire has 30 questions that shows us a pre and postoperative image of the patient, regarding the cognitive, emotional, social functions or regarding the signs and symptoms of the patients, using a scale with more items or singular ones.

The questionnaire, excepting the two last items, can be completed with values between 1 and 4, so,(A) the absolute amplitude of the variation of answer is 3. The scale of life quality is given by the answers at the questions 29 and 30 at which the patients can choose values from 1 to 7, the absolute amplitude being of 6.

Items	Number of items	Number of question
Physical state	5	1 - 5
Daily activities	2	6, 7
Emotional states	4	21 - 24
Cognitive functions	2	20, 25
Social and family relations	2	26, 27
Tiredness	3	10, 12, 18
Nausea and Vomiting	2	14, 15
Pains	2	9, 19
Dyspnoea	1	8
Insomnia	1	11
Anorexia	1	13
Constipation	1	16
Diarrhea	1	17
Financial problems	1	28
General health state	1	29
Life Quality	1	30

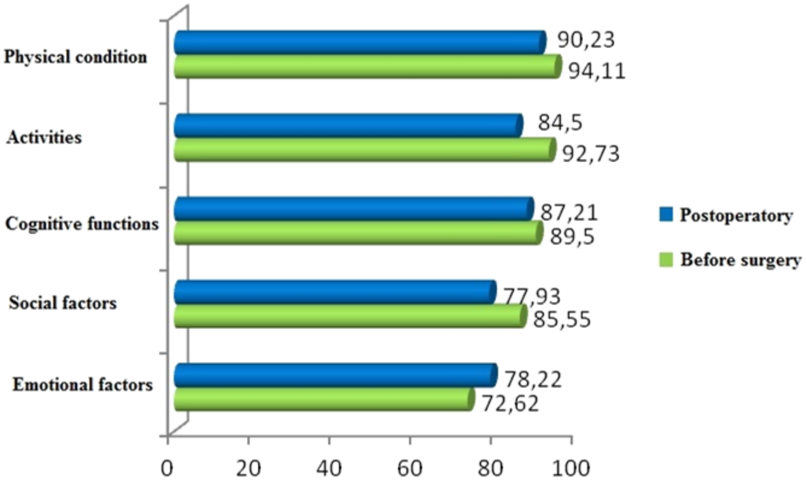
To analyze the questionnaires I used a different formula for functions, namely: Value _functions = 1 – ((Raw score – 1)/Absolute Amplitude)*100 comparing to Value _ symptoms = Raw score -1/Absolute Amplitude)*100.

As a result, I noticed that a higher value of the functions shows a higher rate of functionality and independency, while a higher value of the symptoms shows problems of dependency of the patient.

One can notice in the chart that, only emotionally, the patient feels better after 6 months after surgery. I must mention that the younger patients (<65 years old), consider that, physically and socially speaking, they were better during the preoperative period.

The indicator of the physical state is made up of 5 items: the resistance of hard activities, independency in dressing and eating, as well as the chronicle tiredness and the need of laying in bed. From the questionnaire, one can see that the physical resistance of the patient decreased from 94.11 to 90.23.

Figure 1: Score of life quality regarding functions



One can see an increase of tiredness after prostatectomy, from 11.1 to 16.2 and, also in the symptoms of nausea and vomiting.

The postoperative pain had a significant increase from 10.33 to 12.22.

The tiredness increases proportional with insomnia and the sensation of weakness, and the pain interferes with the daily activities especially at the patients of more than 65 years old.

Figure 2: Score of signs and symptoms

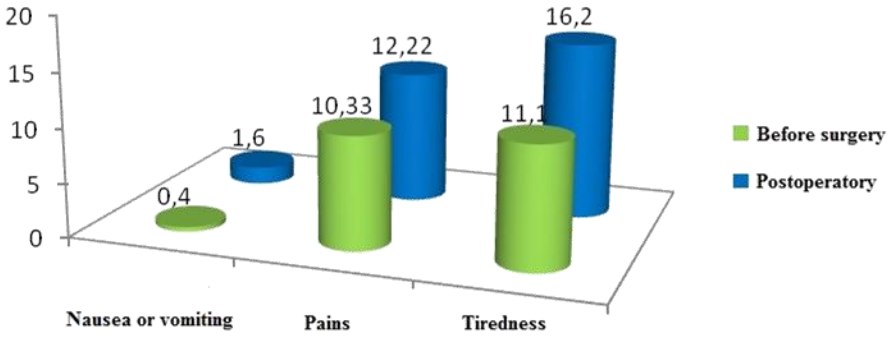


Figure 3: Signs and symptoms

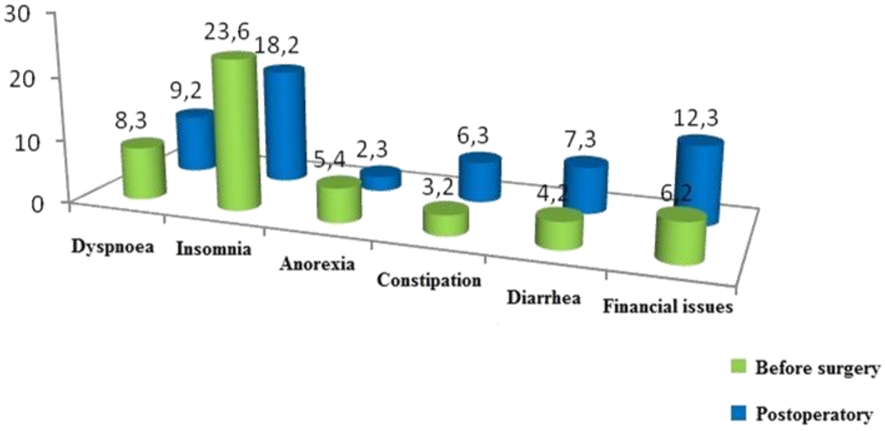

Figure 4: Quality of life

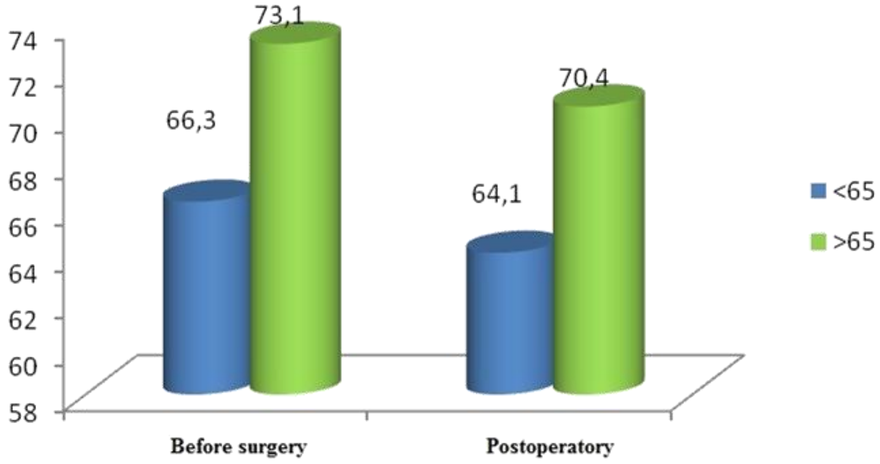

One can see an improvement of the quality of life of the postoperative patient regarding insomnia and anorexia. The digestive symptoms and the financial problems will accentuate postoperatively especially at the patients after 65 years old and the younger ones.

The last items are like a conclusion of the questionnaire permitting the patient to define the last week by the point of view of his health and the manner he sees the quality of his life at a certain time.

Analyzing the data, one can see the most unsatisfied patients on the ground of their physical state and quality of life are the patients younger than 65 years old. Totally, the difference between the quality of life appreciated by people younger than 65 years old pre and postoperative was of 2.2.

Younger patients appreciated the quality of life pre and postoperative lower than the patients of 65 years old.

The EORTC OLO – PR 25 questionnaire contains 25 questions divided into four evaluation functional scales.

Items	Number of items	Number of question
Urinary symptoms scale	9	31-39
Intestinal symptoms scale	4	40-43
Scale regarding the symptoms owing the treatment	6	44-49
Sexual functions scale	6	50-55

The significant differences were regarding the urinary symptoms scale, postoperative 13.86 comparing to preoperative of 7.88. In accordance to the age, there were differences regarding urinary symptoms scale, those of 65 years old had lower scores, at an average of 9.86.

Regarding the sexual functions scale, those younger than 65 had higher scores, at an average of 10.11 units.

The erectile dysfunction appears in a degree of 67% at different levels, while 34.9% shows no affliction of the erectile function.

In the postoperative group 23% presented with mild incontinence while severe and moderate incontinence was present in 4, 7% of the patients.

Postoperatively the frequency of the urinary incontinence was greater in patients older than 65 than those younger than 65.

CONCLUSIONS

To identify the type of treatment is vital for the success of the oncologic therapy of the prostate cancer, though the complications appeared after a radical prostatectomy influences the life quality of the patient. One of the objectives in carrying about patients is in helping at stabilization of the urinary continence and of sexual function, in improving the life quality of the patient. A more critical evaluation of the type of treatment is essential for developing an efficient strategy.

Tumor markers in gastroenterology: useful or useless

Cătălina Diaconu[1], Mădălina Ilie[2], Gaudia Mănescu Avram[1], Laura Voicu[1], Daniel O. Costache[1], Raluca S. Costache[1,2]

INTRODUCTION

Tumor markers are biomarkers that can be found in blood, urine or different body tissues, produced either by cancer cells or normal cells in response to cancer or in different noncancerous conditions (gastrointestinal stromal tumors). Their use varies from cancer screening on a population basis, to staging different tumors or to evaluate the efficiency of the treatment. Most frequently used in gastrointestinal malignancies are: carcinoembryonic antigen (CEA), carbohydrate antigen (CA) 19-9 and α-fetoprotein. However there are many markers that can be useful in dealing with gastrointestinal cancer such as: carbohydrate antigen 125, cyfra 21-1, chromogranin, tumor M2-PK, neuron-specific enolase, smooth muscle actin [1]. Future research show the utility of multiple tumor marker test, when by combining more tests in parallel the predictive value might be increased. For example: when talking about pancreatic or stomach cancer one might combine: CEA, CA19-9 and CA 72-4 [1,2].

ALPHA FETOPROTEIN

So far, alpha fetoprotein is the most studied serological marker in the surveillance of hepatocellular carcinoma, derived from the liver cells and yolk sac [3]. Its' use is debatable. Some studies show that a cut-off of 20 ng/mL carries a sensitivity of 41% to 65% and specificity between 80% and 94%, with a positive and negative predictive value of 25 and 98 percent. Even though The American Association for the Study of Liver Disease (AASLD) guidelines shows that cirrhosis is a possible cause of elevated AFP, its sensitivity (60%) is higher than that of ultrasound (58%). Therefore current data from the literature support the use of AFP combined with ultrasound as the surveillance tests of choice, taken every 6 months, leading to early detection of hepatocellular carcinoma (HCC) [4]. Despite the fact that more than 40% of the patients with HCC have normal AFP, serum levels higher than 500 mcg/L in a high-risk patient is diagnostic of HCC [3,5].

There is a demonstrated correlation between the tumor size and serologic AFP: higher levels with a sudden acceleration appear with HCC that measure more than 3 cm [6]. Moreover serum levels from 1,000 to 10,000 mcg/L are encountered in tumors past 5 cm in diameter. Date from the literature associate high levels of AFP with poorly-differentiated tumors, but further studies are required [7].

False positive values of AFP may be related to flares of activity in chronic viral hepatitis (B or C). Therefore the use of this serologic marker is very important in patients with hepatitis B or C during treatment with nucleotide analogues for hepatitis B or drug acting

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest
[2] Carol Davila University of Medicine and Pharmacy, Bucharest

agents (interferon free) for hepatitis C, when we cannot encounter flares of transaminases [9].

AFP remains an important prognostic marker in patients after resection or in those who are taken into consideration for transplant. High values over 1,000 mcg/L (believed a surrogate of vascular invasion) associates extremely high risks of recurrent disease after transplantation. Moreover some studies assign this value as an exclusion criterion for liver transplantation in patients with HCC that meet the Milan criteria, in order to improve posttransplant outcome [10]. An assay of serum AFT post-transplant is in order every 3 months for 2 years if initially elevated, then every 6 months. This serologic marker remains an independent prognostic predictor of outcome after ortotopic liver transplant for HCC [11].

Table 1: Causes of elevated serum alpha-fetoprotein [8]

Causes of elevated serum AFP

- Hepatocellular carcinoma
- Cirhossis due to hepatitits B/C
- Non-seminomatous germline tumours
- Ataxia-teleangiectasia
- Pregnancy with babies that carry neural tube defects or Down syndrome
- Other gastrointestinal tumours (gastric cancer, biliary tract cancer, pancreatic cancer)

CARCINOEMBRYONIC ANTIGEN

Discovered in 1965, CEA is a glycoprotein associated with colorectal cancer with a rather low sensitivity and specificity. Even though CEA is not used as a diagnostic test, levels over 5.0 ng/mL can predict a unfavorable prognosis, regardless the tumor stage [12].

A Cochrane review showed that a cut-off value of 2.5mcg/L for CEA carries a pooled sensitivity of 82 percent and specificity of 80 percent. For a cut-off of 10 mcg/L the sensitivity lowered to 68%, but the specificity reached 97 percent, due to fewer false positive values. CEA testing should be done once every 3 to 6 months. One must bear in mind the possible false positive values of CEA (most encountered between 5 and 10 ng/mL). One possible cause is due to the adjuvant therapy with fluorouracyl (therefore some recommend the end of adjuvant treatment before measuring CEA).

There are many arguments against using CEA as a screening test such as: almost half of the recurrences of CRC present normal values of CEA; is has no impact on improving survival and the quality of life and it is not cost-effective. One strong argument in favor of testing CEA is the detection of recurrences [13].

Even though CEA is prohibited in the mass screening and diagnostic pathway of colorectal carcinoma (CRC), it has value in the follow-up of patients with diagnosed CRS according to the American Society of Clinical Oncology guidelines: from surgical treatment planning to post-treatment follow-up and prognosis [14,15]. High serum levels of CEA after 4 weeks of the surgery (this being twice the plasma half-life of CEA) indicate the persistence of the disease, occult metastasis and the need to reevaluate the prognosis

[8]. In conclusion, CEA levels can be associated to the TNM classification of CRC, due not only to its prognostic value, but also the decision of adjuvant chemotherapy.

Table 2: Benign and malignant causes of high levels of seric CEA[8,13]

BENIGN	MALIGNANT
Gastritis	Colorectal cancer
Peptic ulcer disease	Breast cancer
Diverticulitis	Lung cancer
Pancreatitis	Gastric cancer
Liver disease	Pancreatic cancer
Chronic obstructive pulmonary disease	Cholangiocarcinoma
Diabetes	
Cigarette smokers	

Studies showed that high CEA even in node negative patients show a worse prognosis, a higher rate of recurrence, therefore adjuvant chemotherapy could be considered [16].

CEA can be used to monitor the response to treatment in metastatic disease. Whilst the decrease of seric levels of CEA shows the favorable response to the treatment, the rising level of CEA is incompatible with tumor regression [8].

Some studies show that bile CEA levels are elevated in cholangiocarcinoma, but not in benign diseases. Used as a single tumor marker, CEA is neither sensitive enough, nor specific enough to diagnose cholangiocarcinoma [8]. Different combinations of CEA and CA 19-9 are used to diagnose cholangiocarcinoma in patients with primary sclerosing cholangitis.

When using cut-off values of 5.2ng/mL for CEA and 180 U/mL for CA 19-9 the sensitivity was 100% and the specificity reached 78%. Despite this, other data from the literature show a sensitivity of 63% for detecting cholangiocarcinoma in patients with PSC, whilst the specificity when using a combined CA 19-9 and CEA only reaches 33%, albeit with higher specificity [13,17].

CARBOHYDRATE ANTIGEN 19-9

Most frequently used serological marker for cholangiocarcinoma, CA 19-9 has a wide variation in sensitivity and specificity. However, values over 1000 IU/mL are encountered in advanced disease with peritoneal dissemination [18].

CA 19-9 levels can be elevated in 45% of patients with non-malignant affliction since the tumor marker is produced by abnormal cyst epithelium. Benign diseases that can be associated with high values of CA 19-9 are: cholestasis, cirrhosis and cholestatic diseases [18,19].

In patients with primary biliary cholangitis CA 19-9 levels can be increased due to cholangitis or biliary obstruction. Literature states that a cut-off value of 100 IU has a 86% sensitivity and a 89% specificity for cholangiocarcinoma [4]. However CA 19-9 remains the most commonly used serological marker in cholangiocarcinoma with a sensitivity of 89% and a specificity of 86% for a cut-off over 100 IU/mL.

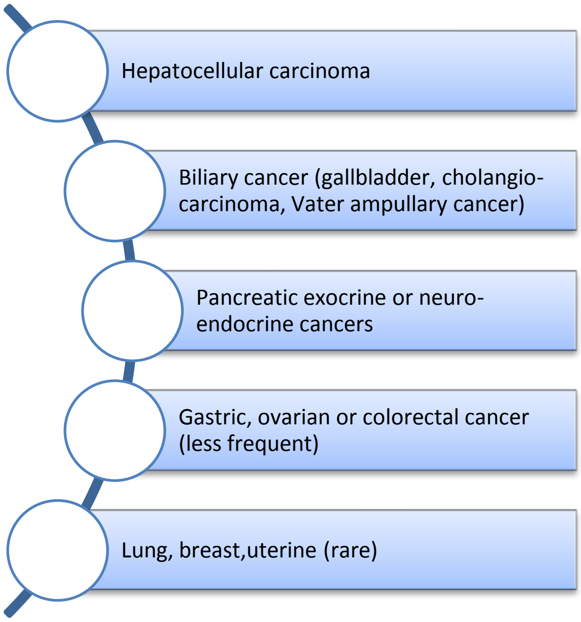
Moreover values over 1,000 IU/mL are associated with unresecability [17].

CA 19-9 has a higher specificity in the diagnosis of cholangiocarcinoma in patients with PBS. Therefore CA 19-9 combined with ultrasound or magnetic resonance cholangiopancreatography (MRCP) are recommended in the annual screening of PBS patients for cholangiocarcinoma [17,20].

Studies shows that the median preoperative CA 19-9 levels in pancreatic adenocarcinoma were 379 IU/mL in patients who would not benefit a curative resection, whilst in patients where it was resected it was 130 IU/mL.

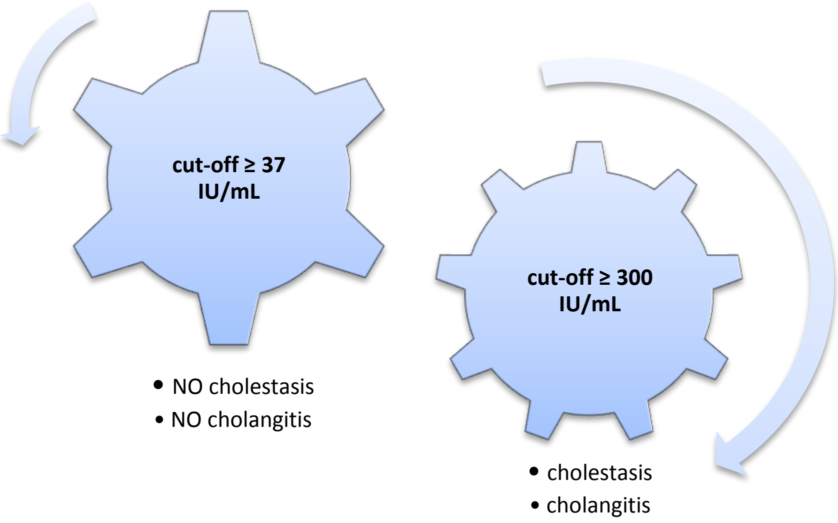
Moreover, values over 130 U/mL postoperative demonstrate unresectability, the likelihood of R0 resection and long-term outcomes [4]. CA 19-9 has a low specificity; therefore studies show that it should not be used as a screening test for pancreatic cancer. However serial testing once every one to three months of this tumor serological marker in the follow-up of patients after curative surgery or in patients with advanced disease that receive chemotherapy was proven useful. Moreover, elevated values of CA 19-9 could precede the radiological images of recurrent disease (must be confirmed with imaging studies or biopsy) [21].

Table 3: Malignant causes of high values of CA 19-9 [18]



Hepatocellular carcinoma
Biliary cancer (gallbladder, cholangio-carcinoma, Vater ampullary cancer)
Pancreatic exocrine or neuro-endocrine cancers
Gastric, ovarian or colorectal cancer (less frequent)
Lung, breast,uterine (rare)

Table 4: Cut-off values for CA 19-9 related to the presence of cholangitis (may associate fever, right upper quadrant pain and leukocytosis) or cholestasis (serum bilirubin larger than 3mg/dL) [18]



cut-off ≥ 37 IU/mL
• NO cholestasis
• NO cholangitis
cut-off ≥ 300 IU/mL
• cholestasis
• cholangitis

In patients that underwent curative surgery, the normalization of the values of CA 19-9 within 6 months is associated with twice the mean of survival than in patients that kept elevated CA 19-9 [17].

In individuals with negative Lewis phenotype (7% of the population), CA19-9 is unreliable since the tumor marker needs the expression of Lewis blood group antigen, leading to a false negative response [21].

Tumor markers could be used to differentiate chronic pancreatitis and pancreatic cancer. CA 19-9 was once used for this purpose, however due to its' low specificity and sensitivity this purpose was forgotten. Despite the fact that CA 19-9 is not used for surveillance in chronic pancreatitis, it can be helpful in families with hereditary pancreatitis [22].

OTHER TUMOR MARKERS

Cancer Antigen 125 (CA 125) is a glycoprotein most frequently used in the diagnosis, screening and prognosis of ovarian cancer, but with a very low sensitivity and specificity especially in early disease. It can have elevated values in non-gynecologic cancers such as: colon, liver, gallbladder cancer [4,8].

Carbohydrate Antigen 72.4 (CA 72.4) is a serological tumor marker used as a specific predictor for clinical recurrence in patients with gastric and colorectal cancer that undergo surgery and to follow up the treatment [23,24]. CA 72.4 with values higher than 7 IU/mL postoperative are associated with a worse prognosis, higher risk of recurrence and higher death risk. Studies show that in stage II colorectal cancer this tumor marker discriminates better than CEA the patients that will relapse or die from those with a favorable prognosis [25,26].

Chromogranin A is a protein contained by the neuroendocrine tumor cells. Elevated values can be encountered in a number of benign and malignant diseases. When referring to gastrointestinal disease we can find high values of chromogranin A in: carcinoid tumors of the gastrointestinal tract, pancreatic neuroendocrine tumors, colon cancer, hepatocellular carcinoma, pancreatic adenocarcinoma, liver cirrhosis, chronic atrophic gastritis, inflammatory bowel disease, and others. Chromogranin A has been associated with treatment response and might have prognostic value in neuroendocrine tumors [4,27].

CONCLUSION

Tumor markers remain a helpful tool in different afflictions. *AFP* is now considered the surveillance test of choice along with ultrasound in hepatocellular carcinoma. *CEA* is not used in the diagnosis of colorectal cancer, but in the prognosis and follow-up after curative surgery. *CA 19-9* is especially useful in the diagnosis pathway of cholangiocarcinoma in patients with PBS. Moreover, values over 1000 IU/ml are highly suggestive for cancer.

INTRODUCTION

Starting September 2010 in Romania the Military Emergency Medical Service (SMMU) was created by the Ministry of National Defense, which has as main mission to provide first aid and save the lives of military personnel during military operations using special equipped MEDEVAC aircraft. Nationwide exist the national emergency system which operates thru 112 emergency number – SMURD (Serviciul Mobil de Urgență, Reanimare și Descarcerare; Mobile Emergency Service for Resuscitation and Extrication) acting in support of the civilian population. In case of accidents with multiple victims the experience has shown the need for collaboration between the two systems, in order to save lives. In the last 5 years there has been an increasing Aeromedical evacuation missions (AME - MEDEVAC) with multiple victims executed by joint civil-military medical teams using military aircraft.

---

[1] 90th Airlift Base Romanian, Romanian Air Forces

This paper provides a review of the most important aspects of particularities, advantages and disadvantages of this type of medical transport using the MEDEVAC missions based study carried out by the Romanian Air Force in recent years.

Performing these tasks presents challenges to mission planning, use of medical equipment and procedures, command-control system, exercise programs jointly joint medical teams and, of course, managing a large number of patients in flight.

The large number of patients transported safely and in the shortest time, regardless of weather conditions recommends this type of medical intervention.

Given the Romanian military presence in various theaters and that NATO strategic medical evacuation is a national responsibility, the capacity of air transport in case of multiple causality is a priority.

In this modern time beside the classical war conflict we are facing more and more new challenges like mass causality due to terrorist attacks, car accidents, fire and explosions in our civilian day by day life.

Due to financial and personnel restraints, neither one of the 2 system, civilian or military one, can properly face by itself this kind of incidents and it's just a question of time until the number of patients will overwhelm the capability and capacity of each system.

In Romania 2 systems coexist for Aeromedical Evacuation: the civilian SMURD (Mobile Emergency Service for Resuscitation and Extrication) using 8 EC135 helicopter and 1 Piper PA-42 Cheyenne III airplane and the military system under de MoD/RoAF command with 6 IAR 330 Puma helicopters and 1 C27J Spartan airplane. The drawback of the civilian system is that there aircraft don't fly at night and in severe meteorological condition. In the military one we don't have enough emergency medical personnel to cover 24/7. So this is the basis on which we start cooperation.

Due to the fact that national evacuation it's a civilian responsibility the military AME assets may be used to augment civil capability in 2 ways: Military aircraft assets with civilian medical crew and Military aircraft assets with mixed civilian-military medical crew.

Military aircraft used in this type of missions are:

- IAR 330 Puma MEDEVAC helicopter: fully equipped as an intensive care unit can carry up to 3 critically ill patient, in all-weather condition day or night with a range of 500 km;

- C130 Hercules has a maximum capacity of 74 stretchers with a range of 2000 km and have been use for years for CASEVAC missions from Iraq and Afghanistan;

- C27 Spartan: the newest and most modern aircraft from RoAF fleet can carry maximum 24 stretchers with autonomy of 6 hours and 2500 km. The characteristic of this aircraft is the possibility of carry 2 special ICU modules with dedicated monitor, ventilator and O2 capability.

Another characteristic is the MEDEVAC pressurization mode in which the aircraft will maintain the cabin pressure at ground level until flight level 130 (4000 m) in order decrease the hypobaric stress on the patient.

The last 6 years statistics show that from a total of 53 MEDEVAC missions with RoAF aircraft 15 (28.31%) where missions with multiple patients with a total of 100 patients (72.46%). The vast majority of this missions were made with C27J Spartan (12 – 80%), 2 with C130 Hercules (13.33%) and only 1 using helicopters (6.66%). That can be explained by the fact that the IAR 330 Puma helicopters can carry only 3 stretcher patient but at this load the space is severely limited. Another factor was the meteorological condition. This type of mission with multiple patients is used on longer distances (more than 300 km) and this is why the fix wing aircraft are used more (speed and distance advantages).

Messaging and alerts: because the civilian medical system can't put on alert the RoAF assets the messaging system goes like this: when somewhere in Romania an accident is happening the initial receiving medical facility contact the secondary or tertiary medical center if the complexity of the injury require a higher level of medical treatment. If the patients or patients are accepted for transfer then the medical coordinator of SMURD send an aeromedical evacuation request to CNMC (National Command Military Centre) who pass it to RoAF COA (Air Operation Component). At this level the Aeromedical Evacuation Officer have an up-to date image of the position, availability and the response time of each aircraft. The decision is made about which type of aircraft (airplane or helicopter) shall be used and the alert message is scrambled.

The particularity of multiple air MEDEVAC mission is that because the number of patients and the diversity of pathology the necessary medical equipment and the component of the medical team on board must be carefully planned on very short notice.

The military medical crew consists normally in 1 or 2 flight surgeons (medical officer, permanent working in an air base, having 1 year course in emergency medicine, 6 month training in aviation medicine, fit to fly according with the medical standards of the National Institute of Aviation Medicine) and 2 to 4 flight nurses (3 years degree in nursing after graduating Nurse College, 6 month training in emergency medicine, fit to fly) but in case of multiple cases this crew can or must be updated with ICU specialist or neonatologist accordingly to the medical need (in June 2012 MEDEVAC mission from Bucharest, ROU to Hanover, DEU with 3 children from 7 day to 3 years old with cardiac malformations in with the crew was upgraded with 1 neonatologist and 2 nurses beside the flight surgeon and the flight nurse from RoAF).

In term of medical equipment due to the national standardization there are no compatibility problems in term of coupling power tension or O_2 pressure. The only real challenge is how to be able to get all the necessary equipment in time and in the right quantity (in July 2008 after a explosion in a Gheorghieni local wood factory we accomplished a MEDEVAC mission for 10 severely burn patients, 2nd 3nd and 4th degree burns, all respiratory assisted and mechanically ventilated so the problem was how to have 10 ventilators and 10 multifunction monitors in that plane in less than 2 hours.)

AEROMEDICAL ASPECTS

Hypoxia is the greatest threat to anyone flying. Physiological effects of hypoxemia can be detected in healthy individuals at lower altitudes of 3000 m but more rapidly in certain patients. It occurs due to changes in ambient pressure. Cabin pressurization reduce this problem especially airplanes, but patients with respiratory failure may be at risk for hypoxemia current cabin altitude achieved. Adjusting the fraction of inspired oxygen to maintain the partial pressure of inspired oxygen constant throughout the mission is a technique useful clinically for prevention of hypoxemia. The wide availability of pulseoximeter decreased incidence of hypoxemia in the MEDEVAC missions with early recognition.

Accelerations: Acceleration or deceleration is a vector quantity, having both magnitude and direction. For this reason, the correct positioning of the patient in the idea to limit acceleration-induced forces sustained should be carried out. Acceleration forces that are experienced in helicopters or planes during routine operations (due to flight techniques and procedures ensuring low range of acceleration forces during MEDEVAC missions) tend to be small in size or as great as those observed in terrestrial transport vehicles.

Volume of gas: ambient pressure decreases with increasing altitude. Pressure changes with altitude and the change can affect a number of medical devices and patients. Contrary to common belief, cabin pressurization does not eliminate the problem. Pressurization allows a comfortable flight altitude manned which could not otherwise be achieved, but in general, not altitude from sea level, and thus, the equipment and the patient will be exposed to a pressure change. Any gas enclosed in a structure therefore becomes a concern. Air trapped in the sinuses, for example, can expand and cause discomfort and equipment (air-filled cuffs) can be damaged or can injure patient with the change altitudes.

Humidity: Humidity is a particular concern in fixed-wing missions because cabin air is taken from the rarefied atmosphere outside, and even in pressurized aircraft and when heated may contain very little moisture. This can lead to dryness and discomfort of the patient secretions during flight.

Noise: Modern aircraft produce quite a lot of noise. In most aircraft cabins is pretty quiet for conversation and patient evaluation but cabins of helicopters are so loud that exclude pulmonary auscultation. Soundproofed helmets and intercom systems are needed.

Vibration: Vibration is a form of repetitive alternative motion. The two major sources of vibration during MEDEVAC missions are powerplant and turbulence of the air moving aircraft. The vibrations cause discomfort and fatigue to patients and also to medical team, and are transmitted to medical equipment in flight and can be the source of errors and monitoring failures.

CONCLUSION

The Multiple victim accidents are a REALITY and the transport of those patients to an adequate level of care facility is a NECESSITY. Air medical transport put additional stress on patients (fear of flying, physical discomfort), on medical staff (unconventional and insufficient workspace with great limitation regarding medical equipment and medication and the impossibility to receive advice and expertise) and on medical equipment (operating in a vibration, pressure and temperature differential environment). Influence appears to be greater for the transport helicopters and in case of multiple patients.

Air medical evacuation missions with multiple victims require: rigorous planning, exercises (based on realistic scenarios) and resources (time, money, personnel, equipment).

Romanian Air Force aircraft equipped MEDEVAC are on alert 24/7 and the training of medical staff allow prompt intervention in case of accidents with multiple victims;

Civil-military intervention can be a solution for those situations, on the condition of legislation harmonization in order to provide fast and efficient mobilization of resources and cooperation between military and civilian institutions.

Finite element analysis of a modified short hip endoprosthesis

Augustin Semenescu[1], Florentina Ioniță Radu[2], Ileana M. Mateș[2], Petre Bădică[3], Nicolae D. Batalu[1]

Abstract: *A finite element simulation of the mechanical static features for a modified short hip endoprosthesis was performed. The corkscrew-like femoral stem was modified introducing more turns of the thread. By such an approach it is expected that for some cases the mechanical fixation of the prosthesis to the bone will be improved or the use of the cement for bonding is not necessary. Our scenario was estimated for titanium and stainless steel, and both materials show good safety factors. Mechanical stress is expected to be distributed more uniform in the bone for the new design with more turns of thread.*

Keywords: *modified short hip endoprosthesis; design; finite element analysis; titanium; stainless steel*

INTRODUCTION

The increase in the average life expectancy rose the age at which different surgical interventions are performed. For example, the total replacement of the hip is made on a typical patient of 60-80 years old, and often patients are older, in some cases even over 100 years old. The primary hip intervention can be followed by several revision surgeries [1,2,3]. This is a reason for designing modular endoprosthesis, where damaged parts can be easily replaced.

A short femoral stem is recommended for patients where the femoral bone allows a minimal resection, and the bone structure has enough mechanical resistance to support the stress induced by implant [4]. A positive aspect of our design consists in screwing the implant into the bone, avoiding its hammering [5,6] that has a high risk of femoral neck fracturing. The prosthesis has a cylindrical metallic body, with an exterior thread, continued with a truncated sleeve, and ended with a junction neck (Figure 1). Inside of the implant there is a hexagonal hole for the insertion of a torque screwdriver (not shown). The distribution holes are built-in and they are intended to be used to spread the cement for fixation after the stem is screwed in the bone.

In this work a modified design is proposed. Namely, more turns (7 instead of 3) [7] of the screw-component of the endoprosthesis are considered. Expectations are to obtain an improved implant-bone fixation and a more uniform distribution of the forces that will allow a longer lifetime with less revision surgeries: it is well known that after about 10-15 years the prosthesis loosens and a replacement may

---

[3] National Institute of Material Physics

be required [8]. For certain cases it is thought that our improved design may also provide a cement-free fixation. Finite-element analysis is used to estimate mechanical features of the prosthesis with the modified design. Two materials, titanium and stainless steel are considered.

MATERIALS AND METHODS

1. CAD design and materials properties

The endoprosthesis was designed [9] in Inventor Professional 2016, and the materials properties were assigned from the software database.

The proposed materials for the endoprosthesis are titanium and stainless steel (Table 1). Materials are considered isotropic and linearly elastic.

2. Mesh settings

All the settings are detailed in [6]. The total number of the resulted elements was 1,694, and the total number of the nodes was 3,287.

Table 1. Mechanical properties of materials used in simulation.

Material	Density [g/cm^3]	Young's Modulus [GPa]	Poisson's ratio	Shear Modulus [GPa]	Yield strength [MPa]	Tensile strength [MPa]
Titanium	4.51	102.81	0.36	44	275.6	344.5
Stainless Steel	8.00	193.00	0.30	86	250.0	540.0

3. Boundary and loading conditions

The endoprosthesis, either the initial or the modified design, is considered fixed on its stem, thread, and under the supporting disk for the scenario when using cement (Figure 1.a, blue region). For the cementless approach only the thread and the part under supporting disk are considered fixed. (Figure 1.b, blue region).

A load of 6000 N magnitude is analyzed, as the most unfavorable case [7]. Both scenarios are studied without the implant/cement/bone interactions.

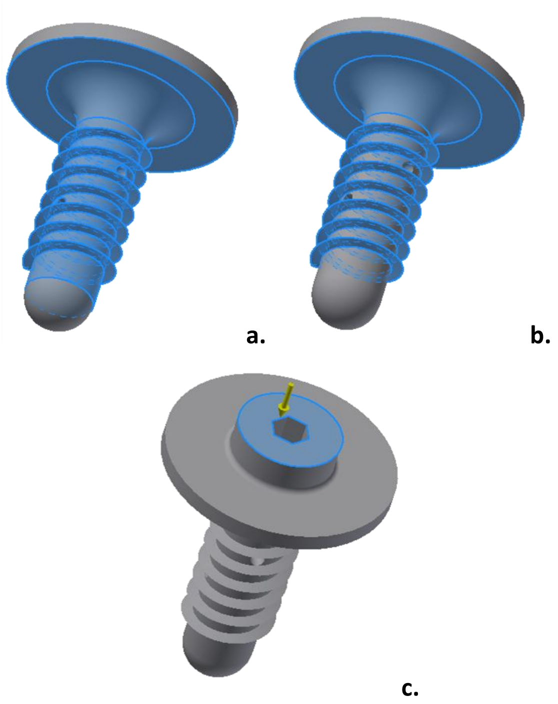
A static compression load is distributed on the upper surface of the disk (Figure 1.c, blue region denoted with an arrow). The safety factor is based on the yield strength.

RESULTS AND DISCUSSION

The simulation results are shown in Table 2 and Figures 3, 4 and 5. The differences between the initial and modified designs are not significant, for selected materials, titanium and stainless steel.

A longer thread suits better for a cementless fixation (Figure 1.b), due to the larger contact area. For the stainless steel, the analysis is shown in Figure 5. The static finite element analysis shows no significant differences when compared to the "cemented" scenario.

Figure 1. Fixed constrained areas of the modified short femoral endoprosthesis: (a) for "cemented", and (b) "cementless" scenarios. (c) Selected area for force distribution.



This approach confirms that the new design does not affect the mechanical behavior of the endoprosthesis. A longer thread is also expected to provide a better stress distribution in the femoral neck and further studies are required.

Table 2. Maximum displacements, maximum Von Mises Stress, and the minimum safety factor for a 6000 N load and different threads.

Materials	Displacement [max, µm]		Von Mises Stress [max, MPa]		Safety factor [min, ul]

CONCLUSIONS

A modified short hip endoprosthesis design is proposed as a better solution than the previous one, where a fixation using cement is considered. The new simple design consists in a longer thread that increases the friction force between endoprosthesis and bone by increasing the contact surface. The finite element analysis shows that the modified design does not affect the mechanical behavior. This design may allow, in some cases, a cementless fixation. Further tests are necessary to confirm our results.

Optical "biopsy" in laryngeal cancer detection

Romeo Costin[1], R. Hainăroșie[2], V. Zainea[2], Corneliu Romaniţan[1], A. Meiuş[1]

INTRODUCTION

Squamous cell carcinomas of the larynx is by far the most frequent malignant tumor of the head and neck region, representing 1-2% of all malignancies diagnosed world-wide. Treatment results of early cancer are not unfavorable: for the reported 5-year-survival rate of Tis, T1, T2 laryngeal cancer patients ranges from 80 to 90% [1]. At present, indirect laryngoscopy is widely used for the evaluation of laryngeal cancer and precancerous lesion, while direct laryngoscopy under general anesthesia with biopsy remains to be the gold standard.

The expression optical "biopsy" has entered into usual speech among researchers in the domain of biomedical optics. In fact this joining of terms is a paradox, because "biopsy" refers exactly to the removal of tissue, while the signification of "optical" is that tissue is not removed. The real meaning of this expression consists in amount of optical measurements mediated by optical fibers which allow the physician to perform an instant tissue diagnosis in vivo, in situ, noninvasively and in real time, previously possible only by using histological analysis. The main reason of this is to avoid the surgical removal of biopsy tissue samples.

These refined optical techniques go beyond standard endoscopic methods by offering improved image resolution, contrast, tissue penetration and delivering biochemical and molecular knowledge about mucosal disorders. For some endoscopic application, for which "random" biopsies are repeatedly taken to discover premalignant or early malignant lesions, optical measurement could enable "guided biopsy", with increased probability for sampling a diseased site, reducing the number of tissue samples. Thus, additional purpose is certified by the potential for reduced health-care costs by eliminating unnecessary histology. Besides, the instant diagnostic information can reduce the emotional trauma to the patient awaiting an answer [2].

Recent technological advances in fiber optics, light sources and detectors have stimulated the tremendous development of many optical methods that promise to notably improve capability to visualize and evaluate human epithelium in vivo [3,4,5]. Some of these techniques are used for detection of laryngeal cancer: fluorescence spectroscopy, optical coherence tomography, narrow-band imaging, contact endoscopy and confocal endomicroscopy. This review describes the basic biophysics of light-tissue interactions, evaluates the strengths and weaknesses of each technique and explores clinical and preclinical evidence for each approach.

OVERVIEW

Fundamental parameters that characterize tissue

optics in terms of radiative transfer are: absorption coefficient, scattering coefficient and anisotropy and measuring those constitutes a central issue in biomedical optics [6].

a. The absorption coefficient (μa) determines the probability of absorption events for a photon that propagates in tissue. Absorption occurs due to coupling of photons energy at a particular frequency with electronic or vibrational transitions energy. Depending on the spectral field, absorption is caused by:
- Cellular DNA and protein (amino acids and nucleic acids) in ultraviolet;
- Specific chromophores (hemoglobin, melanin, etc.) in visible;
- Water, OH and amine infrared.

b. Scattering coefficient (μs) determines the probability of a photon to be scattered during propagation. Scattering is caused by fluctuations of the refractive index of the environment in microscopic scale (ultra-structural heterogeneity) such as water-lipid interfaces membranes inside the cell and surrounding cells and fibers of collagen in the extracellular matrix. We can say that the absorption properties of tissue are tied to tissue biochemistry, while the scattering ones are related to its morphology.

c. Anisotropy (g) is the average cosine scattering angle and weighted the scattering coefficient effectiveness.

d. Alongside the three basic parameters, in medical practice, are also used: attenuation coefficients (total and effective); reflection; the refractive index; reflectance.

Cheong et al [7] realized (1990) a comprehensive compilation of optical tissue properties (absorption coefficients, scattering, total and effective mitigation and anisotropy for different biological tissues at a variety of wavelengths). They concluded that for a specific tissue, large areas of these parameters are frequent, indicating the sensitivity and vulnerability of such measurements to sample variation, detection equipment, boundary conditions and adopted light propagation model. Confidence in the obtained values can be compromised by any of these factors. After 1990, numerous studies have improved this knowledge, creating optical exploration methods that will be presented below.

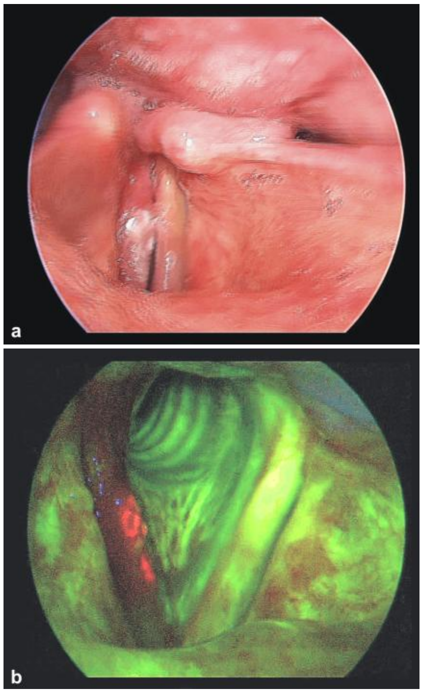
1. Spectroscopy

1.1. Autofluorescence endoscopy (AFE)

Autofluorescence was first observed by Policard [8] in 1924, but Alfano [9] demonstrated in 1984 differences in spectral profiles of cancerous and normal tissues. In the last decades, this technique was used for screening in early detection of cancers of upper- and lower-GI tract and also lower-airway, and recently it was used in identifying precancerous and cancerous lesion [10].

Tissue autofluorescence is based on the presence of endogenous fluorophores, which emit visible green light on appropriate excitation. This involve structural proteins (collagen, elastin) mainly located in the submucosa, but also keratin, porphyrin and enzymes of the respiratory chain such as nicotinamide adenine dinucleotide and flavin adenine dinucleotide within the epithelium [11].

Figure 1: Squamous cell carcinoma of the right vocal fold: White light endoscopy (a); Autofluorescence endoscopy (b) [13]



Because of an altered metabolism in tumor cells, premalignant and malignant tissues show a decreased quantity of fluorophores. Moreover, epithelial thickening prevents the excitatory blue light from reaching the submucosa. Both mechanism results in a loss of autofluorescence, with a color change from green to red-violet [12].

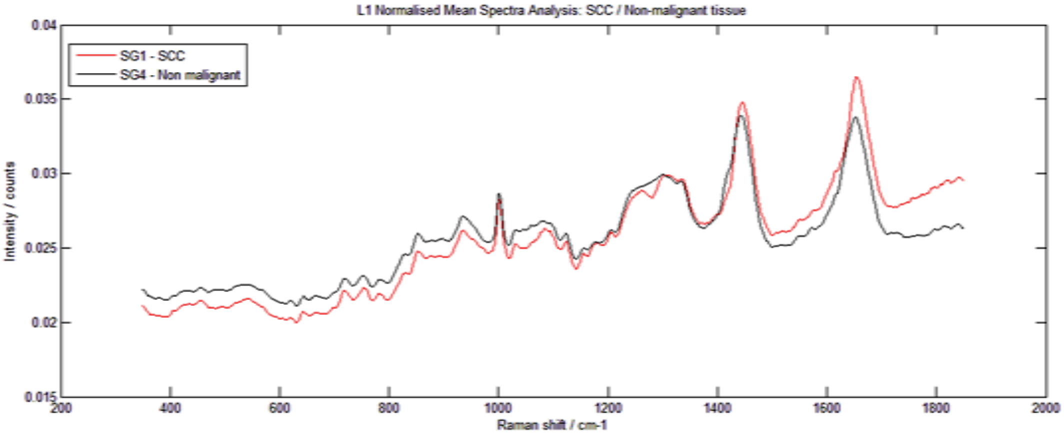
In AFE, healthy mucosa and benign lesion covered by normal epithelium (polyps, nodules, cysts, Reinke's edemas) present green color (no loss of autofluorescence). Scar tissue following surgery or radiotherapy shows a violet color; the same aspect is found in hyperplasia and chronic inflammation.

AFE can be used in early detection of premalignant and malignant lesions, in guided biopsy and oncological follow-up. This technique can only detect changes on epithelium, but not in the deeper structures [14].

Many studies have found that AFE has a better sensitivity and specificity in detecting laryngeal malignant changes than the classic white light endoscopy (WLE) [15,16,17]; a meta-analysis made by Kraft and co. in 2010 concluded: in identifying precancerous and cancerous lesions of the larynx, sensitivity (91% vs. 73%), specificity (84% vs. 79%) and accuracy (88% vs. 77%) of AFE were superior to WLE alone[18]; false-positive diagnoses result from chronic laryngitis, teleangiectatic polyps, granulomas[19] and papillomas; false-negative diagnoses are found in extreme hyperkeratosis, necrosis and inflammation [20,21].

There is a variant of this method involves the study of autofluorescence laryngeal mucosa after topical application of aminolevulinic acid, preferentially captured by the cancer cells, that became colored in orange-red (because protoporphyrin IX), while normal mucosa appear green [22].

Figure 2: Normalized mean and difference spectra for squamous cell carcinoma and non malignant tissue in larynx [26].



1.2. Raman spectroscopy

This method involves an effect whereby a small portion of tissue scattered light has a different frequency from that of the incident beam, with an equal amount of vibration frequencies of the molecules in the tissue; the effect is very weak, but with laser, it is possible to study the movements of rotation and vibration of molecules [23]. From the received signal, the percentage of biological molecules can be extracted in samples, such as collagen, elastin, beta-carotene, cholesterol (fig.2).

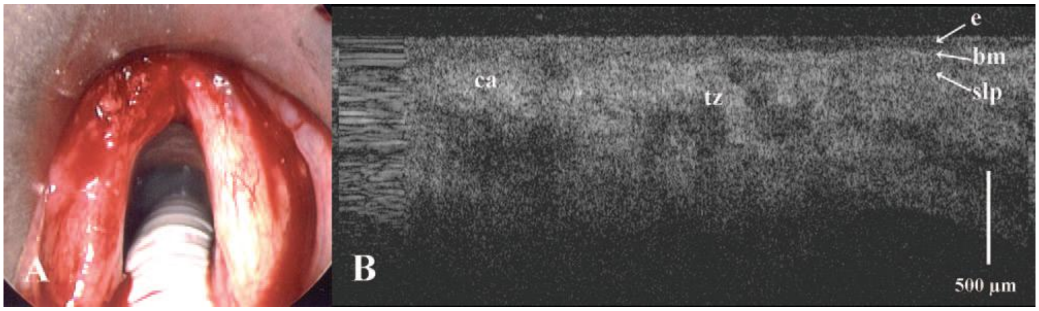
Introduced in medical practice in 2000, Raman spectroscopy is used to differentiate normal laryngeal tissue of precancerous and cancerous lesions [24]. Some authors publishing studies that indicate sensitivity between 70-90% and specificity in differentiating between normal tissues/malignant between 85-95 % [25].

2. Optical coherence tomography (OCT)

OCT is a modern method of investigation, in high resolution, mainly used in ophthalmology. It is derived from low coherence optical interferometry and uses non-ionizing optical radiation in the near infrared field.

OCT allows measurements in real time, in situ, with resolution up to 10 times higher than conventional radiology (CT, MRI), making it possible to identify microscopic tissue structures (villi, glands, crypts, blood vessels). Despite this exceptional resolutions (1-2 µm), the method is limited by the very low degree of depth (penetration of tissue) of 1-3 mm [27]. Articles published in the past decade shows that it can be used to detect an epithelial membrane rupture and overcoming of the laryngeal carcinoma or epithelial thickness measurement (normally between 98-185 µm, about 500 µm in hyperkeratotic lesions) [28].

Figure 3: T2 squamous cell carcinoma of the left vocal fold; (A) Endoscopic photograph. (B) Optical coherence tomography image demonstrating normal epithelium with an intact basement membrane on the right of the image, and invasive cancer with increased backscattering and loss of the basement membrane on the left. A transition zone is seen between these two areas. Note the area of motion artifact on the left of the image (bm-basement membrane; ca-invasive cancer; e-epithelium; tz-transition zone; SLP-superficial lamina propria) [29]



3. Narrow band imaging (NBI)

It is a modern endoscopic technique for investigating the vocal cord that uses certain wavelengths of light to improve the viewing of epithelial and sub epithelial microvascular pattern. They are using wavelengths of 415 nm (blue) and 540 nm (green), which are absorbed by hemoglobin, causing epithelial microvasculature to be colored in brown and become visible. The obtained images can be improved and recorded by using a HD (High-Definition) video system [30,31].

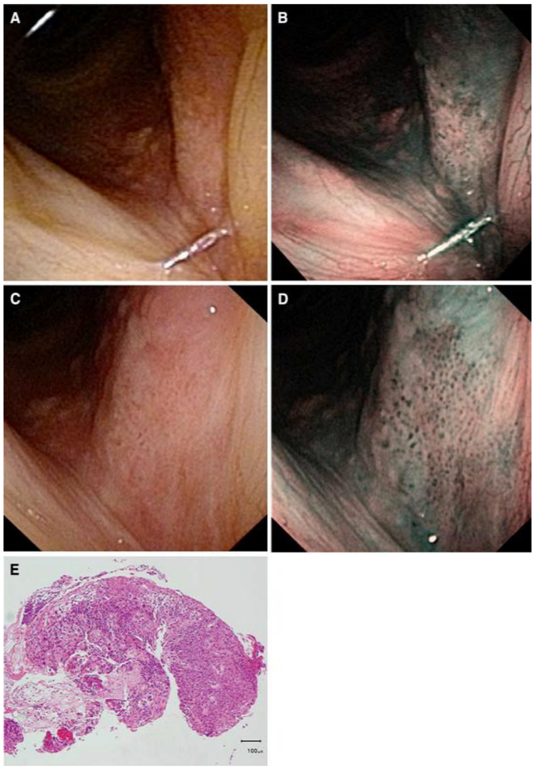
Neoplasia suspicion rises when on a brownish area, well-marked, is observed thick dark spots and/or tortuous course of the microvasculature, or more, a hypertrophic blood vessel that branches in small vascular loops [32,33]. There are studies that demonstrate that this optical method can even make the difference between neo-vessels specific to carcinoma and the ones altered by post-radiation inflammation [34].

The method was originally used for early detection and monitoring post-surgery esophageal [36], and tracheobronchial [37] neoplasm lesions, but recent studies show that is gradually earning supporters using it for the same goals at the larynx [38,39] (good results in subglottis injuries). Thus, Japanese authors demonstrate that narrow-band imaging has a sensitivity of 91.3% and a specificity of 91.6% [40], in laryngeal cancer lesions, while a team from Italy (Brescia) reports 90% specificity and 98% sensitivity [41].

Another recent study [42], multicenter, prospective, randomized, which included patients with esophageal cancer and pharyngeal and laryngeal cancer, showed that narrow-band imaging compared with conventional endoscopy detected a higher number of superficial carcinomas synchronous in both locations, making them the authors to conclude that this method could be the standard examination for early detection of superficial cancer in those localizations.

But the interpretation of the images must be made by an ENT specialist with a good experience, to avoid false negative or false positive. Also false negative may occur on lesions where the keratin layer has a greater thickness.

Figure 4: A. Conventional white-light image of the larynx. The left subglottic region is displayed slightly reddish. B. NBI image of the same site as a. Demarcated brownish area is seen in the left subglottic region surrounded by green area. C. Close white-light view of a. D. Close NBI view of b. There are scattered brown spots in the lesion. E. Histopathologic evaluation of the biopsy specimen revealed moderately differentiated squamous cell carcinoma of the larynx [35].



4. Confocal endomicroscopy

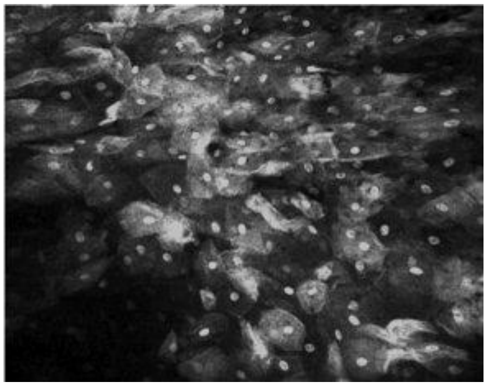
This technique is introduced into medical practice in 2004 by R. Kiesslich for in vivo diagnosis of colorectal cancer[43]. The principle of the method consists in illuminating the examined tissue with a laser wave of 488 nm which allows viewing epithelium in depth up to 250 µm. For a better image quality is given intravenously a contrast substance (fluorescein). The examination is made simultaneously with both endoscopic and endomicroscopic, acquiring images to identify the characteristics of epithelial cells (size, shape, appearance of the nucleus) near the basal membrane [44].

The limitation of this method is shallow penetration (250 µm), knowing that the cancer epithelial thickness can reach 500-1000 µm, being unable to view the membrane. Also it requires a pathologist with experience.

Introduced recently in Otolaryngology, there are still no studies on a large number of cases, but those in the gastrointestinal field [45,46] give high hopes for the future of this method.

There is a pilot study [47] clearly demonstrates the possibility to detect dysplastic cells near to the basal cell layer and within the subepithelial space in lesions with small leukoplakia (thin keratin layer). These results can have an impact on microlaryngoscopy to improve the precision for biopsy and on microlaryngoscopic laser surgery of the larynx to identify the margins of the pre-malignant lesion.

Figure 5: Confocal endomicroscopy image of the human supraglottis captured in vivo following topical application of 0.05% acriflavine hydrochloride [48]



5. Contact endoscopy

Contact endoscopy is another novel noninvasive optical diagnostic imaging method that allows in vivo and in situ examination of the cellular architecture of the superficial layers of the mucosal epithelium. Magnified images are obtained using Hopkins' rod-lens endoscope placed on the surface of the dye stained mucosal tissue. This method allows evaluation of precancerous and cancerous lesions in vivo and has significant potential in the histopathologic diagnosis of many suspicious head and neck mucosal lesions without tissue biopsy. The first reported use of CE in otolaryngology head and neck surgery was by Andrea et al. as a diagnostic tool in the evaluation of various pathologies in the larynx in the 1990s [49]. They were able to visualize and diagnose laryngeal mucosal pathology from the magnification of vocal fold epithelium and microvasculature during microlaryngoscopy after staining the vocal cords with methylene blue dye.

Few members of our group [50] have systematically drawing vascular changes of the vocal fold, with clinical and pharmacological applications. They demonstrated the changes of microvascularity, occurring since stage of hypertrophic chronic laryngitis (hypervascularity with dilated vessels, but parallel to the free edge of the vocal fold) till the carcinomatous lessions (with hypervascularity and areas of keratin, changes of the archaeological and cytological parameters: **U**niformity of the cellular-field, **R**atio (nucleus/cytoplasm), **S**ize and **S**hape of the epithelial cells [51].

There are more advantages of contact endoscopy. Most significantly, it offers a noninvasive, quick, and repeatable in vivo evaluation of the cytological architecture while avoiding the need for an invasive biopsy and its associated risks. CE provides immediate results, with the possibility of examining many mucosal areas in a short time. CE can also assess a wider surface mucosal area, providing more information than a selected histological section taken by biopsy [52]. It also avoids tissue damage and alteration of cellular architecture which may occur in the biopsy and histological preparation. Subsequently, this results in a dramatic improvement of the diagnostic yield of the biopsy. Other potential roles of CE include the rapid diagnosis of benign and malignant mucosal lesions in an outpatient or operating room setting, surveillance, guided biopsies, and intraoperative evaluation of tumor resection margins. Despite its advantages, CE does have its limitations. Most notably, CE can only evaluate the most superficial cell layer of the mucosal epithelium. This is most likely due to a number of factors including (i) poor penetration of methylene blue which only stains a few superficial layers, (ii) short focal distance of the scope (i.e., CE can only assess to a depth of 80 um at 60x magnification and 30 um at 150x magnification), and (iii) optical artifact at high magnification due to glare from light reflected from cells not in focus. The lack of depth of penetration prevents the evaluation of important histological information especially when vertical extent of dysplasia is crucial in distinguishing the different grades of dysplasia from carcinoma in situ and invasive carcinoma. As a result, these factors could affect the sensitivity of CE, thus accounting for some of the false negative diagnostic results noted by authors. The potential impact of CE missing a malignant lesion needs to be taken into consideration if this technology is to one day substitute histopathology. Future investigation into better penetrating dyes, advances in digital optics, and image enhancements will eventually allow better vertical staining and increased resolution of the deeper cell layers which would translate CE in becoming a much more sensitive and accurate diagnostic tool.

Detection of epidermoid squamous-cell carcinoma by laser induced autofluorescence – preliminary results

Romeo Costin[1], Tatiana Tozar[2], V. Zainea[3], Ruxandra Pîrvulescu[4], I. R. Andrei[2], R. Hainăroșie[3]

Abstract: *Epidermoid squamous-cell carcinoma is by far the most common malignant tumor of larynx (95-96%), representing 1.6-2% of cancers in men and 0.2-0.4% of malignancies in females, with a world growing incidence and a slight dominance in urban areas. By exposing cells and tissues to UV light, the excitation of naturally occurring chromophores occurs in part by non-radiative deactivations, in part via fluorescence emission. Using laser induced autofluorescence (LIAF) in natural tissues not impregnated with photosensitizers as a noninvasive autofluorescence technique for both diagnosis and intraoperative assessments of laryngeal cancer we can improve the tumor malign identification in vivo. A total of three laryngeal biopsies (i.e. three pairs of tissues, each pair containing a healthy and a tumor tissue sample extracted from the same patient) were considered in this study. The samples were collected from patients previously diagnosed with stage T3 laryngeal carcinoma. Immediately after the surgery fragments of normal tissue and neoplastic tissue were collected, fragments of which later, after freezing, were sectioned in 25-30 µm thickness slices and stretched to quartz slides. All samples were subjected to controlled laser irradiation using a pulsed diode laser (λ=375nm, pulse width=87ps, frequency 31MHz) and the autofluorescence and its lifetime were collected using two optical fibers (inner diameter 400µm and 1500µm, respectively) positioned in a 45° geometry. The signals were recorded using a spectrograph and a photo-sensor module, the output of which was fed to a digital oscilloscope.*

We assessed the impact of laser induced autofluorescence and autofluorescence lifetime measurements in order to identify the differences between healthy and tumoral laryngeal tissue and outlining them, in terms of differences between the laser autoinduced fluorescence averaged intensity. The results determined the usefulness of laser induced spectroscopy in the diagnosis of laryngeal squamous cell carcinoma, discriminating between the malignant and normal tissue by analyzing the differences in spectral autofluorescence intensity and autofluorescence lifetime.

INTRODUCTION

Cancer is a growing dilemma in the developed countries. Laryngeal carcinoma is the most common cancer of the head and neck. Epidermoid squamous-cell carcinoma is by far the most common malignant tumor of larynx (95-96%), representing 1.6-2% of cancers in men and 0.2-0.4% of malignancies in females, with a world growing incidence and a slight dominance in urban areas [1].The main risk factors are smoking, alcohol consumption, harmful dietary habits, exposure to the irritant chemical substances [2].

Early identification and pre-operative evaluation of laryngeal carcinoma and its precursor lesions are essential for function-preserving surgical treatment. Accurate determination of the site and extent of carcinomas is very important for planning therapy and establishing prognosis [3]. Attempts to optimize diagnostic methods to obtain more sensitive detection and precise description of laryngeal pathology remain a challenge for the otolaryngologist [4].

Microlaryngoscopy with biopsy is the standard diagnostic procedure for the detection of laryngeal carcinoma. Anyway, the microscopic view added to the palpation of the larynx is not always enough to the evaluation and precise description of precursor lesions. Some new techniques, like videostroboscopy, contact endoscopy, confocal endomicroscopy, optical coherence tomography, narrow-band imaging and fluorescence endoscopy have been developed to come up with the detailed examination and the histopatological information about mucosal lesions [5,6].

Fluorescence is a optical phenomenon of the light emission by some molecules after their excitation by the light at a particular wavelength. These fluorescent molecules are called fluorophores. Every fluorophore exhibits its characteristic absorption and emission bands whose shapes and positions of their maxima on the excitation and emission light wavelength axes depend on the physical and chemical properties of its nearest environments. The interest in the use of fluorescence in medical diagnostics has grown during the last decades. Fluorescence spectroscopy provides information on the biochemical and morphological aspects of different tissues [7].

The procedures using the fluorescence spectroscopy for the differential diagnosis of malignant lesions are based upon the differences in the autofluorescence emission due to the pathological changes of the tissue. These changes include the modifications of tissue architecture (tissue layer loss or thickening), light absorption and scattering by neovasculature, and the alterations of metabolic status of the tissue such as changes of the concentration and distribution of fluorophores [8]. As a result, recorded fluorescence emission spectra of cancerous lesions reveal differences in fluorescence intensity and fluorescence band shapes, when compared to healthy tissue.

MATERIALS AND METHODS

The spectroscopic measurements were investigated in three larynxes from laryngectomized cancer patients treated in ENT Clinic, Carol Davila Central University Emergency Military Hospital, Bucharest. Histological analysis of the tumor tissues revealed laryngeal epidermoid squamous-cell carcinoma (SCC) in both cases, stage T3 (Figure 1). Immediately after the surgery (total laryngectomy), the larynx was carefully washed in saline solution to remove any blood contamination.

After that, fragments of normal tissue and neoplastic tissue were collected, fragments of which later, after freezing, were sectioned in 25-30 µm thickness slices and stretched to glass slides (reconfirmed histological) and stored at -80ºC for further examination. All participants provided written consent to participate in the experiment. The study was approved by the local ethics committee.

Experimental setup (Figure 2) was performed using laser beam exposure of the samples a picosecond pulsed laser diode (Alphals, type PicoPower LD-375-50) emitting at 375 nm with 31MHz pulse repetition rate, 87 ps full time width at half-maximum laser pulses, and the average power of about 0.5 mW. A laser beam of 1.6x1.8 mm (elliptical) diameter was sent to the sample in double-pass vertical irradiation geometry through a 355 nm dichroic mirror and a totally reflecting mirror.

Two types of measurements on tissue samples were performed: laser induced autofluorescence (LIAF) and autofluorescence life-time. The autofluorescence signal was collected using two optical fibers positioned each, at 45° in the same plane with respect to the pumping laser beam.

Acton SpectraPro 2750 spectrograph
Photo-amplifier Hamamatsu (rise time 0,5 ns)
Tektronix oscilloscope

The optical fiber with the core diameter of 400 µm collects the signal for LIAF spectrum analysis; another fiber of 1,500 µm collects the remitted signal for autofluorescence life-time analyses. The LIAF signals were recorded using a spectrograph (Princeton Instruments, type Acton SpectraPro 2750) with an optical resolution of 0.08 nm and; a photosensor module (Hamamatsu, type H6780-20) having 0.78 ns rise time, was used for LIAF life-time measurements and its output was fed to a digital oscilloscope (Tektronix, type DPO7254). The signal acquisition by spectrograph and photosensor module was synchronized with the laser pulse through a pulse delay generator (SRS, DG 535). During the LIAF measurements, the probe (sample and substrate/slide) was placed on a XY manual stage with a displacement resolution of 5 µm. Each type of measurement was performed collecting the LIAF signal from three different spots for each sample. For each healthy and tumoral tissue two slides with the same type of samples were prepared.

RESULTS

The LIAF spectra of the healthy and tumoral tissues are presented in Figures 3-5 and are compared in terms of peak intensity (*I*), Area (*A*) under fluorescence spectral distribution curve and ratio between the intensity and the corresponding full width at half maximum (*I/FWHM*) signal.

In case I, two healthy tissues of different thicknesses, 20 µm and 30 µm, were compared. Figures 3A and 3B presents the LIAF spectra of the three spots from the duplicate samples and Figure 3C shows the corresponding averaged spectra. The peaks of LIAF spectra are placed between 456 – 462 nm for the 30-µm tissue thickness and between 460-463 nm for the 20-µm tissue thickness. In Figures 3A and 3B are observed variations in peak intensity, area and I/FWHM and approximately the same values for FWHM. These variations are, dominantly and most probably, due to different concentrations of fluorophores in the samples. The comparison between the averaged spectra of 20 µm and 30 µm shows 11.4% autofluorescence intensity, a 9.5 % area and a 14.4% I/FWHM increase in 30 µm with respect to 20 µm case.

Figure 3. Case I. LIAF intensity for healthy tissue for different thickness: A) 20 µm and B) 30 µm; collected in three spots of the duplicate samples and the averaged spectrum; C) LIAF intensity of the averaged spectra from the 20 µm and 30 µm thickness samples.

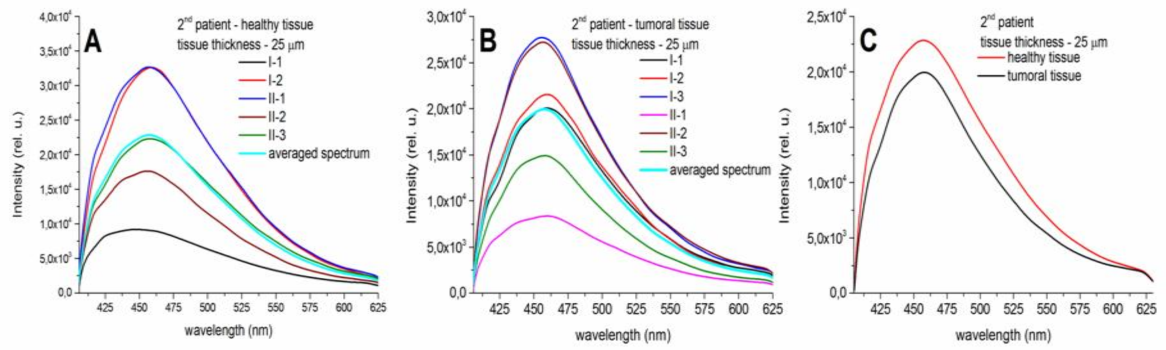

Figure 4. Case II. LIAF intensity for 25 µm tissue thickness: A) healthy and B) tumoral; collected in three spots of the duplicate samples and the averaged spectrum; C) LIAF intensity of the averaged spectra from the healthy and tumoral samples.

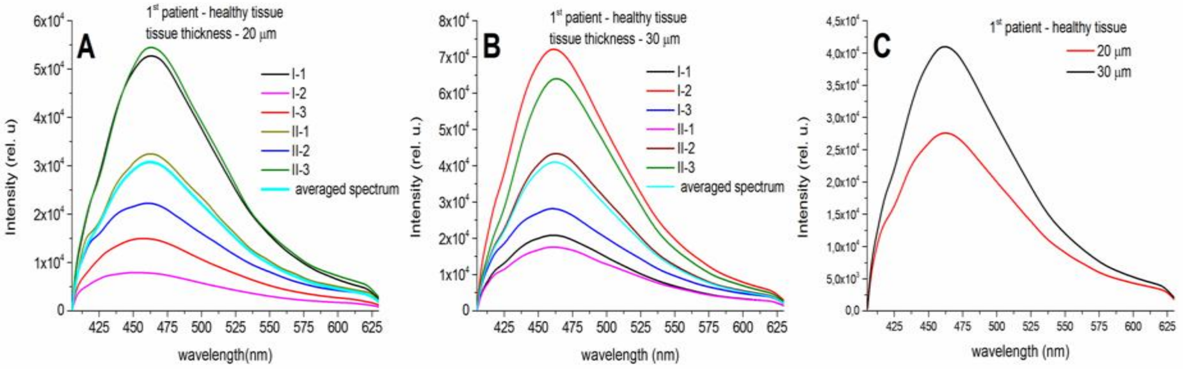


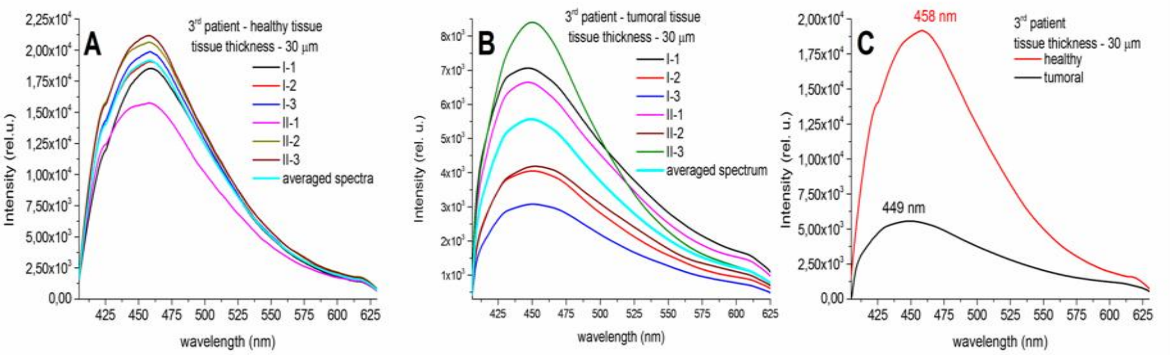
In case II, one healthy and one tumoral tissue of 25-µm thickness were analyzed. Figures 4A and 4B present the LIAF spectra of the three spots from the duplicate samples and the corresponding averaged spectrum (Figure 4C). The peaks of LIAF spectra are placed between 445 – 462 nm for healthy tissue and between 456 – 459 nm for tumoral tissue. In Figures 4A and 4B, are observed variations in peak intensity, area and I/FWHM and approximately the same values for FWHM.

In general, the maximum value of LIAF's intensity is smaller for the cancerous tissue (with 16.7%) than the healthy one. The area and the I/FWHM ratio of LIAF for cancerous tissue is also smaller than for healthy tissue (with 17.1% and 4.7%).

In case III, one healthy and one tumoral tissue of 30-μm thickness were analyzed. Figures 5A and 5B present the LIAF spectra of the three spots from the duplicate samples and the corresponding averaged spectrum (Figure 5C). The peaks of LIAF spectra are located between 457 – 458 nm for healthy tissue and between 456 – 459 nm for tumoral tissue. In Fig. 5A and 5B, are observed variations in peak intensity, area and I/FWHM, but smaller than those from case II, and approximately the same values for FWHM.

In Figure 5C, the maximum value of LIAF's intensity is smaller for the cancerous tissue (with 71%) than the healthy one. The area of LIAF for cancerous tissue is also smaller than healthy tissue (with 66.7%). At the same time, maximum spectrum for tumor sample is shifted to blue with nine nm (449-458 nm) than healthy tissue and the I/FWHM ratio decreases with 74.2% when comparing the healthy tissue with the tumoral one.

Figure 5. Case III. LIAF intensity for 30 μm tissue thickness: A) healthy and B) tumoral; collected in three spots of the duplicate samples and the averaged spectrum; C) LIAF intensity of the averaged spectra from the healthy and tumoral samples



The computed parameters based on the experimental data extracted from LIAF spectra for the 2nd and 3rd patient healthy and tumoral tissues are shown in Table 1.

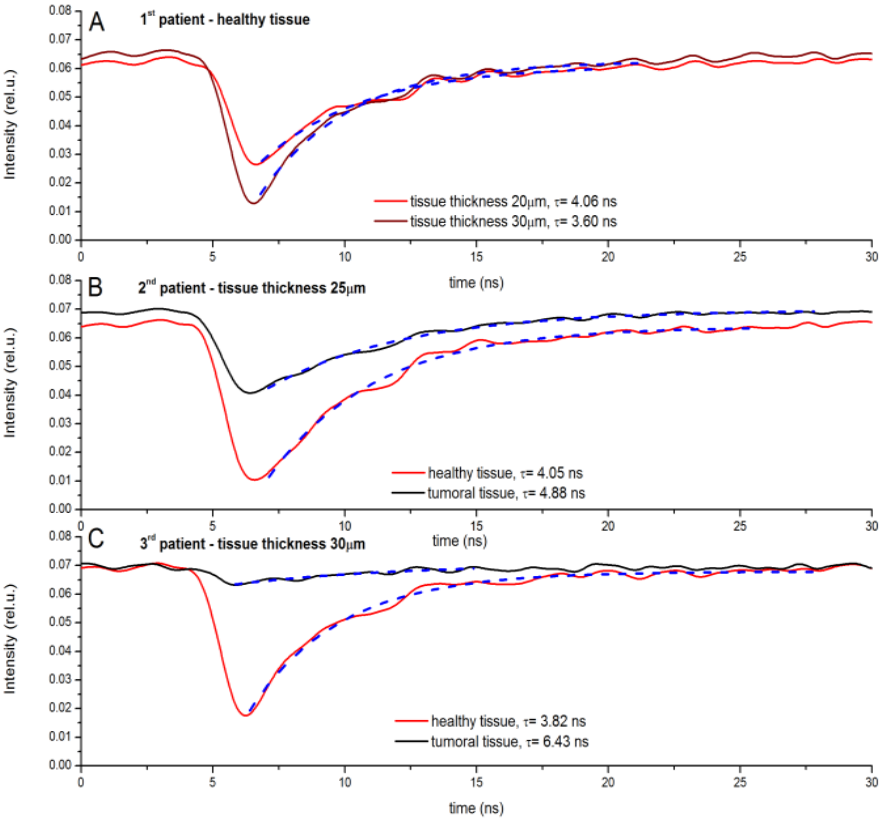
The results indicate that values of LIAF's parameters (wavelength, intensity, area, I/FWHM) are helpful and complementary diagnostic tools in detection of laryngeal carcinoma. These variations are due to the different concentrations and distribution of fluorophores in the samples.

Table 1. Parameters extracted from LIAF spectra for the 2nd and 3rd patient healthy and tumoral tissues (rel. u. are different from one column to the other; the same values of rel.u. are used for different patients)

Patient	Tissue	λ_{peak} (nm)	I_{max} (rel. u.)	FWHM (nm)	Area (nm x rel.u.)	I/ FWHM
2nd	Healthy	457	$2.29x10^4$	107.48	$2.58x10^6$	212.6
	Tumoral	457	$2x10^4$	98.5	$2.13x10^6$	202.5
3rd	Healthy	458	$1.92x10^4$	101.69	$2.07x10^6$	188.5
	Tumoral	449	$5.56x10^4$	114.6	$6.87x10^6$	48.56

Regarding LIAF's life-time (Figure 6), performed measurements show that the life-time of the healthy tissue decreases with thickness increasing, both for first patient case (Figure 6A) and for the second and third patients (Figures 6B and C, respectively). In Figure 6A, the life-time value decreases from 4.06 ns for the tissue of 20 µm thickness to 3.6 ns for that of 30 µm thickness, both values being obtained by averaging 4 samplings.

Figure 6. LIAF's life-time. A) 1st patient, healthy tissue at two thickness, 20 and 30 µm; B) 2nd patient, healthy and tumoral tissues at 25 µm tissue thickness; C) 3rd patient, healthy and tumoral tissues at 30 µm tissue thickness; blue dash line indicates the exponential decay fit function whose time constant τ represents life-time of the analyzed process.



It is to mention that the life-time values of healthy tissue for second and third patients are similar with those for the first patient considered for the same tissue thickness. For both patients exhibiting developed malignant tumor, the life-time values were higher for the cancerous tissues than the healthy samples (4.88 vs 4.05 ns for second patient; 6.43 vs 3.82 ns for third patient) as we see in Figures 6B and C.

DISCUSSION

The prognosis for patients with laryngeal cancer is significantly better with early detection of malignant lesions. Therefore, otolaryngologists look for supplementary techniques, as laser-induced autofluorescence, which may improve accuracy of real time cancer detection.

Malzahn et al. [9] have demonstrated high sensitivity of autofluorescence endoscopy in the diagnosis of early laryngeal cancer compared with light endoscopy alone. In the study of Zargi et al. [10] the sensitivity and specificity of described method were 86.9% and 82.8%.

The aim of the presented study was to analyze the applicability of laser-induced autofluorescence measurements to the differentiation of the changes in the cancerous and healthy tissue of the larynx. For the measurements, it was used a laser diode emitting pulses of picosecond duration and λ = 375 nm. The chosen wavelength was found to excite the endogenous fluorophores: tyrosine (max. emission at 310 nm), tryptophan (max. emission at 340 nm), oxidized form of nicotinamide adenine dinucleotide (NAD+) (max. emission at 460 nm), the collagen cross-links (max. emission at 420–460 nm), the reduced form of nicotinamide adenine dinucleotide (NADH) (max. emission at 460nm), and the oxidized form of flavin adenine dinucleotide (FAD) (max. emission at 520 nm) [11]. The levels of the mentioned fluorophores, especially NADH and FAD, provide a strong emission signal and are significantly altered in cancerous cells, enabling the differentiation of the healthy and neoplastic tissues by autofluorescence measurements [12, 13, 14].

In both cases of the study, the LIAF's intensities of the cancerous tissue samples are lower in comparison with the adjacent healthy tissue samples. These results are in accordance with other studies where the decrease of intensity may be a consequence of reduced concentration of oxidized flavoproteins, the breakdown of collagen cross-links, the thickening of the cancerous tissue or the blood absorption (neovascularisation, inflammation)[15,16]. Neoplastic cells infiltrating submucosa express matrix metalloproteinases activity, which participate in breaking collagen cross-links [17].

We also observed in both cases that the area of LIAF for cancerous tissue is smaller than healthy tissue, the value of the ratio Intensity/ Full width at half maximum (I/FWHM) decreases in cancerous tissue sample and maximum spectrum for tumor sample is shifted towards blue. As for LIAF's life-time, in both cases the values were higher for cancerous tissues than healthy samples. Measurement of these parameters gives to our study originality, as well as the experimental setup.

Our results indicate that LIAF's parameters values (intensity, area, I/FWHM, life-time) are potentially a very helpful, complementary, diagnostic tool in detection of laryngeal carcinoma. The clinical prospective research on a great number of patients should be performed to establish utility of these measurements in everyday practice.

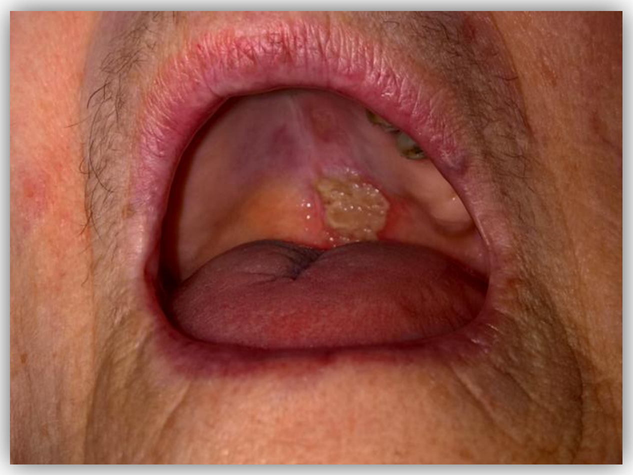
Mucous herpes zoster in elderly

Daniel O. Costache[1], Ionel Țoropoc[1], Ciprian Jurcuț[1], Cătălina Diaconu[1], Laura Voicu[1], Raluca S. Costache[1,2]



78 years old female is admitted in hospital for low back pain with moderate dysfunction and headache, secondary associated with vesicular/ pustular and ulcerative lesions in the mouth (image).

The patient has a cardiovascular medical history with severe arterial hypertension, grade 1 atrio-ventricular block, paroxistic atrial fibrillation, mitral and tricuspidian regurgitation, congestive heart failure NYHA II and chronic renal disease stage IIIB.

Biologic findings shows slight normochrome anemia, WBC was within normal range and no signs of inflammation. Ag Hbs, Ac anti HVC, HIV were negative. Beta haemolitic streptococcus and staphylococcus aureus were absent.

The imagistic standard evaluation (ultrasound) has normal findings.

Patient developed an erythematous patch on the soft palate, with pustules and ulcerations, slightly painful, and some vesicles on the left side of the tongue. No lymphadenopathy was present. It was interpreted as mucous herpes zoster and Acyclovir treatment, 4 grams daily for 7 days was initiated. From the 5th day the subjective symptoms disappeared and local manifestations tend to diminish.

Herpes zoster is the result of VZV reactivation and its spread from a single ganglion to the neural tissue of the affected segment and the corresponding cutaneous dermatome. When the virus is located and multiplies in the geniculate ganglion, facial, aural, and oral lesions of herpes zoster may emerge. Reactivation in the geniculate ganglion can lead to facial nerve (VII) paralysis (because sensory and motor nerves conjoin in nerve VII). VZV and HSV account for the majority of cases of Bell palsy (idiopathic facial paralysis). Our case was not one of those.

Under treatment, evolution was favorable, and 1 month after stopping treatment there were no residual symptoms.

Syrian war shrapnel injury: cubital nerve defect grafting during humanitarian surgical mission. Clinical case presentation

Argentina Vidrașcu[1], **Paul Polihovici**[2]

Abstract: *Background and aim of this clinical case presentation is to reveal the importance of early nerve injury diagnosis and surgical treatment in war wounded patients.*
Methods. The author treated patients in Amman Charity Hospital were among different plastic surgery cases where limb nerve injuries with nerve grafting indication. The presented case was treated with autologus sural nerve graft.
Results were evaluated at 3 months after the surgery and revealed detectable nerve conductibility at the Electromiography test.
In conclusion, in cases with delayed nerve repair surgical treatment in war wounded patients, the vascularised nerve graft can be a better solution for nerve defect surgical treatment.

Keywords: *NERVE injury, axonotmesis, war wounded patient, sural nerve graft, microsurgery, ulnar claw.*

CASE REPORT

Acute and chronic war wounded Syrian refugees from Zaatari camp and the Syrian battlefields are directly admitted in Amman Al Maqqased Charity Hospital every day.

Among patients treated by the author during November 2015 Humanitarian Mission was a left cubital nerve defect due to a bomb explosion injury.

Peripheral Nerve injury described by Sunderland classification can be: neuropraxia as the lowest degree of nerve injury in which is affected only the nerve conduction and no disruption is done. The second degree is axonotmesis where the axon is damaged but the surrounding tissue remains healthy (1). The most severe form of nerve lesion is neurotmesis where both the surrounding tissue and the axones are disrupted (2).

Patient's surgical and medical history

Female patient, 42 years injured 8 month prior to surgery. Immediately after the explosion the patient received first aid surgical assistance: wound cleaning and direct closure.

The patient felt on the first postoperative day that she completely lost the tactile sense on 4th and 5th fingers on her injured left hand.

---

[1] Constantin Papilian Military Emergency Hospital Cluj - Napoca
[2] Iuliu Hatieganu University of Medicine and Pharmacy Cluj Napoca

During the healing process, the wound infection and sutures opening occurred and the patient was treated with antibiotics and wound dressings until the wound has completely closed.

Two months after the injury she was examined and diagnosed with post traumatic cubital nerve injury.

Clinical and paraclinical information

The patient presents left cubital nerve chronic palsy with "ulnar claw" appearance and extensive (12 cm) longitudinal scar on the palmar aspect of the forearm (Figure 1). The metacarpophalangeal joints of the 4th and 5th fingers are extended and the interphalangeal joints of the same fingers are fixed in extension.

Figure 1: Left hand war injury with antebrahial wound and hypothenar region muscular atrophy.

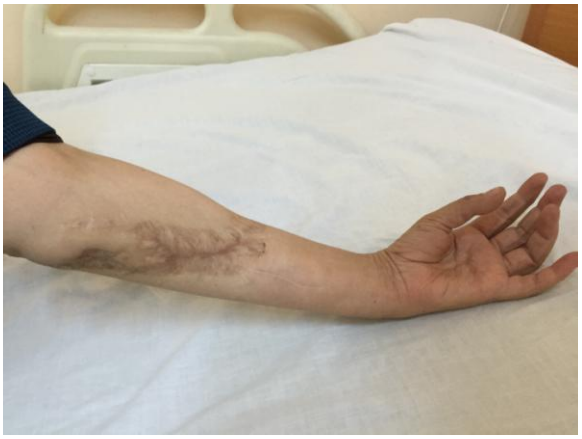

Figure 2: Ulnar claw hand aspect with insufficient flexion of the 4th and 5th finger's interfalangial joints.

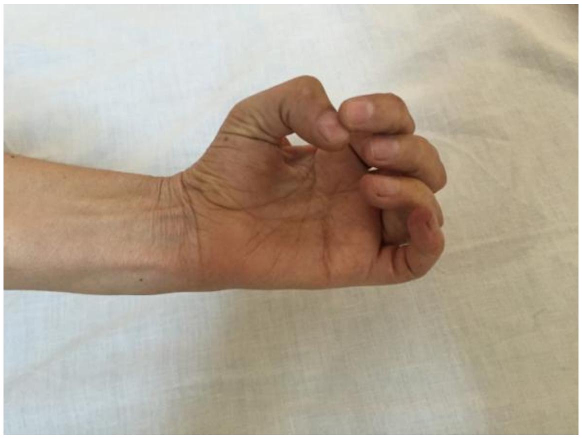
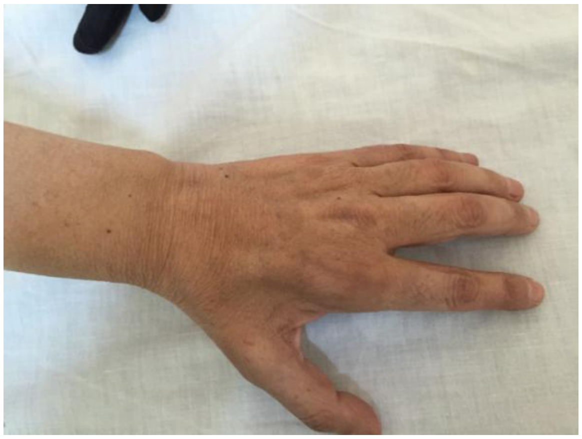


The claw is most obvious when the patient is asked to flex all fingers: the 1st and 3rd digits are flexing due to intact medial nerve innervation and the 4th and 5th ones are remaining extended because of high cubital nerve injury (Figure 2).

The final diagnosis is clarified by dorsal and hypothenar regions denervation and atrophy and by Electromiography testing which reveals the left ulnar transmission is completely disrupted at the scar site (Figure 3).

Figure 3: The dorsal aspect at the cubital denervated hand with muscle atrophy.



The nerve injury is grade 5 according to Sunderland's system.

Surgical method

Clinical practice and research on nerve injury treatment indicates that the primary surgical repair during the first week is required. If the nerve is disrupted on more than 2 cm length the sural nerve graft must be done.

The surgery was performed under general anesthesia using an interfascicular microsurgical nerve suture technique.

The partial scar excision was done and fibrosis was devided.

Cubital nerve was found being disrupted on 10 cm length at the medial 1/3 of the forearm. After debridement and neurolisis due to myeline degenerative process, the gap real size was 14 cm long (Figure 4).

The autogenous sural nerve grafting was decided to be done.

The right 18 cm long sural nerve graft was harvested and a cable graft designed to bridge the gap (Figure 5).

Figure 4: Cubital proximal and distal nerve stump after surgical debridement.

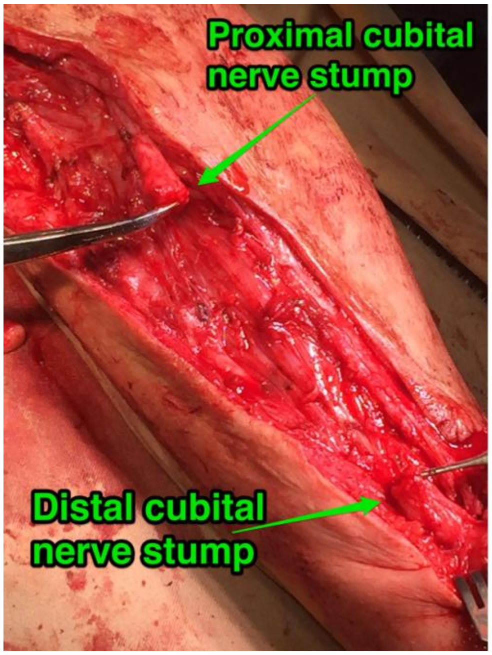


Figure 5: Right Sural nerve graft harvested.

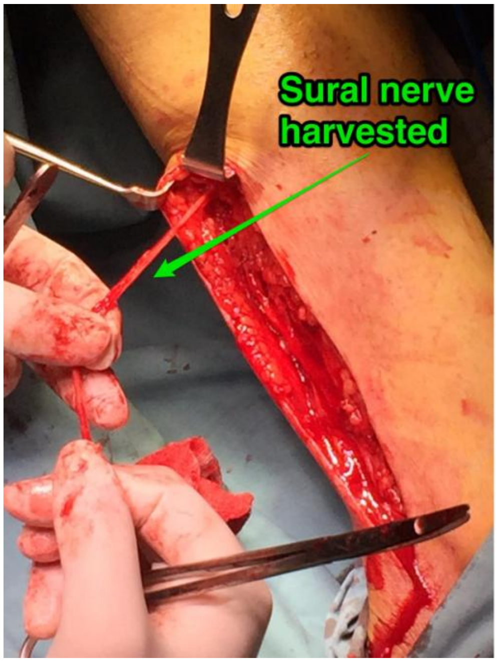


The microsurgical sutures were done at the both nerve ends to achieve nerve connections with separate nonabsorbable 7-0 sutures (Figure 6).

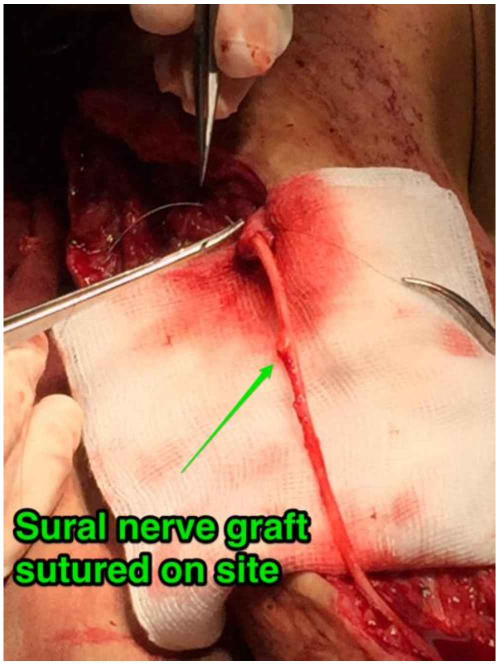
Skin suture and hand splinting was done.

The patient's evolution was favorable under antibiotic therapy for 7 days with no wound closure complications.

Results

After 3 months of kinetotherapy and electrotherapy the nerve conductibility was evaluated as being detectable at the lowest level by Electromiography test. No sensitivity or lightning in the 4th and 5th fingers was detected.

Figure 6: Sural nerve graft sutured on site.



Continued hand therapy rehabilitation is indicated and, 6 and 12 months postoperative evaluation by Electromiography and two point discrimination tests are mandatory at each following checkup.

DISCUSSION AND CONCLUSION

The nerve injury repair should undergo in most of the cases on the emergency surgical treatment basis.

In neurotmesis cases the immediate surgical repair attitude (one week) is the preferred approach for nerve defect treatment in order to obtain a high sensitive and motor functions recovery rate (3).

In chronic palsy (lasting > 3-4 months) associated with muscle weakness, atrophy, surgical outcome is less certain. The duration of palsy and muscle weakness are key factors influencing the prognosis (4).

No conservative treatment can be done in such cases just bridging segmental nerve defect with autogenous nerve graft or decellularized nerve allograft and nerve tubulisation in repairing defects less than 5 cm (5).

In present case the grafting was done 8 months after surgery – this may lead to a less motor recovery but sensitive recovery still can be a good one 6 months after continuous hand rehabilitation(6-8). This demonstrates that 3 months after surgery the cubital nerve conduct was detected even at the lowest level.

In war areas where patients cannot seek specialized medical attention immediate after the injury and their nerve palsy is diagnosed later on, a vascularized nerve grafting should be considered as a clinical alternative for nerve reconstruction if sensitive sense it is not improved after nerve grafting.

Further research comparing late nerve grafting versus vascularized nerve grafting must be done.

The not so good and the not so bad

Silviu V. Dumitrescu[1]

Today's question: How good is the good cholesterol?

Since before med school we knew that is a bad cholesterol and a good one. And like old days vigilantes we fight the bad one and support the good. But, like the characters in the novels, the bad one seems to have a bright side and the good one has dark secrets.

First let's talk about the LDL. It's involvement in atherosclerosis it’s a fact and it's a silent killer. The cardiologists are fighting it since 1987 when the introduction of lovastatin in ischemic cardiac disease.

Figure 1: The good and the bad cholesterol [5].

Now let's talk about the sheriff, HDL cholesterol. The one that protect us in the front of vascular aggressors. We know that the bigger is the better and we are very sad when our patient have low levels of it. But 500 years ago we knew that the earth is flat, so what is the truth?

Recently 4 Big Pharma firms developed a new class of was a real breakthrough. But what the neurologists have to say? After the initial enthusiasm was tempered they started to ask: our patients have a LDL cholesterol level way below 70 mg/dl. They are safe. But they look dumber. Why? The statin lead to a mental decline or the low LDL level is to blame? In my opinion is the LDL level. I noticed that in several of my patients with very low LDL levels: they develop very fast dementia symptoms that regress dramatically when their LDL levels rise above 70 mg/ml. Is it a coincidence? Maybe. But what if the bad has good side?

lowering cholesterol drugs – Cholesteryl Ester Transfer Protein Inhibitors (CETPi) that were announced to be the new milestone in the treatment of dyslipidemia. Preliminary studies showed a spectacular HDL levels rise.

First to go first to fall – torcetrapib – shortly the mortality increased from an unknown cause.

Next dalcetrapib and evacetrapib – HDL levels reached the top. Well tolerated, few side effects, no increased mortality.

Then the bomb dropped: the studies were shutdown prematurely. Why? Headmaster of the late ACCELERATE study, Steve Nissen declared for Forbes magazine that “the drug didn’t work". I don't think that was the accurate response. In my opinion the drug worked because patients achieved incredible high HDL levels. The problem was that despite these very high HDL levels the cardiovascular events were not different from the placebo group. So I would say that drug proved to be effective in what it was made to do but high HDL levels were useless.

---

[1] Acad. St. Milcu Medical Diagnostic and Treatment Outpatient Centre, Bucharest

Here comes the question: is the HDL as protective as we used to believe or just handsome good-for-nothing cholesterol as suggested by those studies?

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related "mini-series" of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors'

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research

must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

EDITORIAL

About health, with hope

Dan Mischianu

Gral (R) Prof DAN MISCHIANU
Chief of Urology Clinic, Carol Davila Central Emergency Military Hospital
Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Health is an extremely complicated subject, but to talk about health is like howling in a cave: anyone can hear, no one understands! ...maybe only the echo?!

The World Health Organization (WHO) proposed in 1948 when it was established, the following definition: "Health is a fully favorable physically, mentally and socially status, not merely the absence of disease or infirmity." Then came an addition: 'ability to lead a productive life, socially and economically. "

I recently finished reading a bestseller also promised to the Romanian reader by Polirom publisher "Sapiens A Brief History Of Humankind" Yuval Noah Harari, Vintage Books, London, 2014. A strange creature this "homo sapiens" is, strange since all his derivatives propose other approaches and other perceptions on the concept or "health"! To primordial "sapiens" health had other connotations...

Perhaps they were cleverer, crueler, and that is why they prevailed and multiplied logarithmically. Then the diseases appeared: congenital, posttraumatic, neoplastic, infectious and so on...

Returning to our nation, Romanians produced with unmistakable grace many sayings, in which they truly believe: "Health is better than all!", "Health is the best wealth!"

Or, pessimistically "Until you're sick, you cannot be healthy!"

The traditional stories regarding health record something else: "Health, contentment and trust are your most valuable possessions and freedom is the greatest joy of yours."

I am absolutely convinced that we all want to reach or to "apply" (Anglo-Saxon term) to an entity which we believe is intangible: "Health comes first!"

Unfortunately, after we solve almost all our goals and desires, we find that health left at the end, it is "unsolvable"!...

Romanians deep and law abiding Christians, ancestral pessimistic have another saying "Cherish health when you lose it!"

Even I do not understand this allegory, why?

Because I work in a field that many pretend to understand, but few have deciphered the "anatomy and physiology" of its development, an area where financiers who led it wanting to make a profit, now keep their mouths shut nor can i forget that there were great men, deciding the destiny of many nations, who had a absolutely unfortunate history of "health": Emperor Napoleon III died in urosepsis under the supervision of the most famous urologist of its time, Emperor Wilhelm II, the first grandson of Queen Victoria of the United Kingdom, born with left brachial plexus palsy after a labor dystocia (1859), "irritable, angry, violent and passionate" started The First World War and Generalissim – Iosif Vissarionovich Stalin's apparently had the same malady that which made him as reckless and cruel.

They followed, and still follow many others, the bad, and the complexed!

It is these thoughts that make me not to forget Miron Costin's assertion: "There are times under the man, but the poor man under these times." ("Chronicle of Moldavia after Aron Voda").

For this editorial, unfortunately slightly skeptical about the future, it will appear in the new year 2017 I ask the reader of these lines to believe and hope that Romania will benefit from a new configuration of a credible, effective and with a tendency towards the many health system.

I further wish you a happy New Year full of accomplishments, or, as people say in our country, “A Happy New Year!"

Article received on March 7, 2016 and accepted for publishing on August 25, 2016.

Capabilities for identification and confirmation of bacterial biological agents

Diana M. Popescu[1], Marius Necșulescu[1], Lucia E. Ionescu[1], Simona N. Bicheru[1], Gabriela V. Dumitrescu[1], Viorel Ordeanu[1]

Abstract: *Military Medical Service is able for detection, identification and confirmation of biological agents; it is part of medical protection against CBRN weapons. We are specialized capabilities for in vitro tests, under construction, the maximum containment laboratory designed for work with Risk Group Microorganisms. An efficient primary containment system must be in place, consisting of one or a combination of the following: Class III safety cabinet laboratory, passage of two doors, suit laboratory, controlled access, controlled air system. Negative pressure in the facility, supply and exhaust air must be HEPA-filtered, decontamination of effluents, sterilization of waste and materials, airlock entry ports for specimens, materials and animals must be provided etc. Complementary is an Animal facility for in vivo tests. This is suitable for work with animals that are deliberately inoculated with microorganisms in Risk Group.*

Keywords: *biological security, military capability, biological attack, biological agents, CIMIC, medical protection*

CAPABILITIES FOR IDENTIFICATION AND CONFIRMATION OF BIOLOGICAL AGENTS

Military Medical Service is abilities for the detection, identification and confirmation of biological agents. It is part of the medical protection against CBRN weapons, with mobile and stationary capabilities. MMRC participate, specifically the medical protection against biological weapons and bioterrorism with a series of microstructures: Biological mobile intervention team with mobile platform; Biological analytical laboratory CBRN defense, integrated platform for scientific and medical-military research for biological agents, with: Laboratory of Microbiology high secure, Secured animal facility laboratory for confirmation of biological agents, laboratory of molecular biology and genetics, toxicology laboratory and Annex facility. [1, 2, 3, 4]

SPECIALIZED CAPABILITIES

Stationary

The maximum containment microbiological laboratory is designed for work with Risk Group Microorganisms, for in vitro diagnostic. Operational maximum containment laboratories should be under the control of national or other appropriate health authorities. [5,

---

[1] Military Medical Research Center, Bucharest

6]

Laboratory design and facilities:

- Primary containment. An efficient primary containment system must be in place, consisting of one or a combination of the following; Class III cabinet laboratory. Passage through a minimum of two doors prior to entering the rooms containing the Class III biological safety cabinet is required; [5, 7] Suit laboratory. A protective suit laboratory with self-contained breathing apparatus differs significantly in design and facility requirements from a Biosafety Level 4 laboratory with Class III biological safety cabinets. [5]

- Controlled access. The maximum containment laboratory must be located in a separate building or in a clearly delineated zone within a secure building. Entry and exit of personnel and supplies must be through an airlock or pass-through system. [5, 8, 9, 10, 11]

- Controlled air system. Negative pressure must be maintained in the facility. Both supply and exhaust air must be HEPA-filtered. There are significant differences in the ventilating systems of the Class III cabinet laboratory and suit laboratory. [5]

- Decontamination of effluents. All effluents from the suit area, decontamination must be decontaminated before final discharge. Heat treatment is the preferred method. Effluents may also require correction to a neutral pH prior to discharge. Water from the personnel shower and toilet may be discharged directly to the sanitary sewer without treatment. [5, 8, 9, 10]

- Sterilization of waste and materials. A double-door, pass-through autoclave must be available in the laboratory area. Other methods of decontamination must be available for equipment and items that cannot withstand steam sterilization. [5, 6]

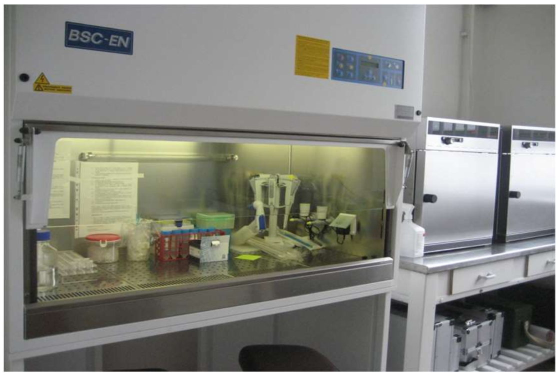
- Airlock entry ports for specimens, materials and animals must be provided. [5]

- Emergency power and dedicated power supply lines must be provided. [6]

- Containment drains must be installed. [5]

Because of the great complexity of the engineering, design and construction of Biosafety Level facilities, in cabinet or suit configuration, schematic representations of such facilities have not been included. [5] (Figure 1)

Figure 1: Microbiological laboratory for biological agents



Animal facility

This is suitable for work with animals that are deliberately inoculated with microorganisms in the Risk Group, for in vivo diagnostic. [12, 13, 14] The following safety precautions apply:

- All the requirements for animal facilities – Biosafety Level must be met. [12, 13, 14, 15]

- Biohazard warning signs (see Figure 1) should be posted on doors and other appropriate places. [12, 14]

- The facility must be designed for easy cleaning and housekeeping. [12, 14]

- Doors must open inwards and be self-closing. [12, 14]

- Heating, ventilation and lighting must be adequate. [12, 14]

- If mechanical ventilation is provided, the airflow must be inwards. Exhaust air is discharged to the outside and should not be recirculated to any part of the building. [12, 14]

- Access must be restricted to authorized persons. [12, 14]

- No animals should be admitted other than those for experimental use. [12, 14]

- There should be an arthropod and rodent control program. [12, 14]

- Windows, if present, must be secure, resistant to breakage and, if able to be opened, must be fitted with arthropod-proof screens. [12, 14]
- After use, work surfaces must be decontaminated with effective disinfectants. [12, 14]
- Biological safety cabinets (Class II) or isolator cages with dedicated air supplies and HEPA-filtered exhaust air must be provided for work that may involve the generation of aerosols [12, 13, 14, 15, 16]
- An autoclave must be available on site or in appropriate proximity to the animal facility. [12, 13, 14, 15, 16]
- Animal bedding materials must be removed in a manner that minimizes the generation of aerosols and dust. [12, 13, 14]
- All waste materials and bedding must be decontaminated before disposal. [12, 13, 14]
- Use of sharp instruments should be restricted whenever possible. Sharps should always be collected in puncture-proof/-resistant containers fitted with covers and treated as infectious. [12, 13, 14]
- Material for autoclaving or incineration must be transported safely, in closed containers. [12, 13, 14]
- Animal cages must be decontaminated after use. [12, 13, 14]
- Animal carcasses should be incinerated. [12, 13, 14]
- Protective clothing and equipment must be worn in the facility, and removed on leaving. [12, 13, 14]
- Hand-washing facilities must be provided. Staff must wash their hands before leaving the animal facility. [12, 13, 14]
- All injuries, however minor, must be treated appropriately, reported and recorded. [12, 13, 14]
- Eating, drinking, smoking and application of cosmetics must be forbidden in the facility. [12, 13, 14]
- All personnel must receive appropriate training. [12, 13, 14]

This facility is complementary to the microbiological laboratory (Figures 2, 3).

Figure 2: Animal facility for microbiological diagnosis

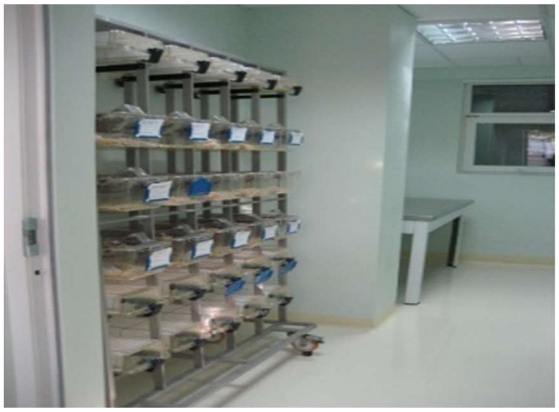


Figure 3: Secured animal facility laboratory

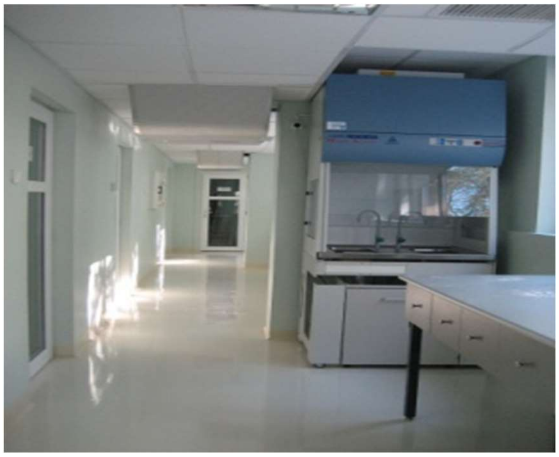


SPECIALIZED MOBILE CAPABILITIES FOR Bio-Det SYSTEM

Specialized Mobile capabilities for Bio det system:

- provides monitoring, sampling, detection and identification;
- detects long line releases and identifies up to 6000 species and sub-species (data base).
- up to 96 samples can run simultaneously, no time needed to re-deploy.
- deploy worldwide and conduct biological surveillance operations in order to provide identification of biological agent employment.
- provide information to other forces (rescue teams, medical, etc)

Bio-Det Systems

Configuration:

- Vehicle with 2 internal compartments, with power supply, specific furniture and safety cabinet class III.

For monitoring: Verotect – determines if a bio-mass is present within aerosol particles of a certain size range

For identification:

- MALDI TOF Microflex LT 20 with vehicle mount
- Water, soil and air sampling kits
- Sample preparation equipment (incubator, centrifuge, freezer, autoclave, handling tools, consumables and reagents)

Miscellaneous:

- Personal protection for the operators (suits, masks, oxygen tubes)
- Hardened laptop etc.

Mass Spectrometry

Those are complex instruments which record an ionic flow as a spectrum, in relation to both mass and the relative occurrence of the ions; Mass spectrometry is a confirmation analytical technique which allows identification of organic compounds, based on the mass/electrical charge ratio of the molecule fragments of the analyze.

The mass spectrometer consists of 4 elements: sample loading port, where a certain amount of sample is introduced at the required pressure in order to be exposed to the ion source and to be ionized at maximum efficiency. Ion source, where the neutral atoms and molecules are ionized and directed into the instrument as a monenergistic bundle.

Mass (energy) analyzer, which by electrical and/or magnetically deflections selects the ions according to the q/m values, their masses, concomitantly focusing them towards an outlet gap. Detector, comprising the system which transforms the ionic flow either into a photographic image or an electric current that can be recorded with an appropriate instrument.

MALDI TOF Microflex

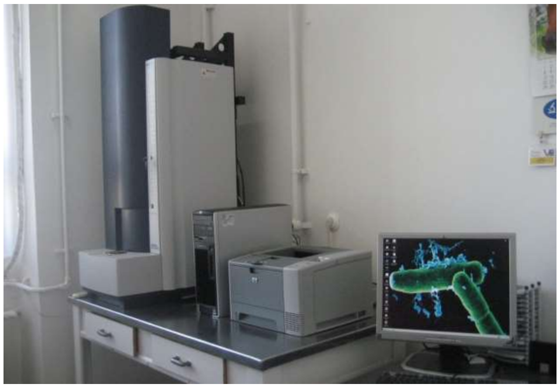
Microflex LT20 is a MALDI TOF system equipped with Bioprofiler software and it is used for the identification and taxonomic appointment of the biological agents from air, water, soil and other surfaces, after a previous specific processing of the collected samples. The main element is a MALDI TOF spectrometer, with a mass domain from 2,000 to 20,000 Da. The instrument is controlled by means of a computer with Windows operating system and specialized software (Bioprofiler). The data processing system controls all acquisition, saving and storage processes of the spectral information, allowing later processing of the information or access to the data base.

Microflex LT 20 Bruker system

It has the ability to identify the biological agents from various samples (liquid, solid, gaseous). Identification is performed by comparing the obtained spectrum to the existing data base of memorized biological agents.

The software indicates the matching of the spectrum under test with spectra from the database, according to the obtained scores. Scores are generated by evaluation and comparison between spectra and are not percents. If a biological agent is not included in the data library, the agent with the closest structure is exhibited, but the score indicates that the agent under test is not included in the data base of the instrument (Figure 4).

Figure 4: Mass spectrometer for microbiological diagnosis (The Microbiology Laboratory MMRC, I. Cantacuzino)



Operation steps Microflex

Preparation of samples for MALDI TOF analysis is done by extracting 16S ribosomal proteins that can be achieved by several techniques depending on the organism analyzed. [17]

The instrument can measure mass spectra from 2,000 up to 20,000 Da, i.e. a very wide range of organic molecules originating from any kind of biological agents (bacteria, spores, viruses, fungi, yeasts, toxins). The software and its data base are capable to identify biological agents of civil and medical-military interest.

The equipment is foreseen with a device for attachment to mobile laboratories, allowing its use in the field, either in campaigns or, in peace time, in case of biological events or crises.

The quality of the incorporated mass spectrometer as well as the structure of the soft that can be upgraded in time, strongly recommends the MALDI TOF – Bioprofiler MICROFLEX LT20 system for identifying biological agents, to be used for precise microbiologic diagnostic, species confirmation for the biological agent, medico-military research and medical defense against biological weapons or bioterrorist attacks.

Military Medical Service is able for detection, identification and confirmation of biological agents. It is part of medical protection against CBRN weapons, in civil-military cooperation (CIMIC). [17]

CONCLUSIONS

CCSMM has specific capabilities for scientific research for medical protection against CBRN WMD.

Anti-infective medical protection laboratory and Epidemiologic emergency laboratory have capability of performing detection, identification and confirmation of biological agents within the limits of available supplies.

The capacities and capabilities of health protection against biological weapons are interoperable with NATO.

Detection, identification and confirmation of the presence of bacterial biological agents are executed sequentially and modular, specialized capacities through cooperation, which must have the capability to perform these tasks.

The consequences of Chernobyl accident

Ion Chioșilă[1]

Abstract: *These days marks 30 years since the Chernobyl nuclear accident, followed by massive radioactive contamination of the environment and human in Belarus, Ukraine and Russia, and resulted in many deaths among people who intervened to decrease the effects of the nuclear disaster. The 26 April 1986 nuclear accident contaminated all European countries, but at a much lower level, without highlighted consequences on human health. In special laboratories, the main radionuclides (I-131, Cs-137, Cs-134 and Sr-90) were also analyzed in Romania from environmental samples, food, even human subjects. These radionuclides caused the population to receive a low dose of about 1 mSv in 1986 that is half of the dose of the natural background radiation (2.4 mSv per year). As in all European countries (excluding Ukraine, Belarus and Russia) this dose of about 1 mSv fell rapidly by 1990, reaching levels close to ones before the accident at the nuclear tests.*

Keywords: *nuclear accident, Chernobyl disaster, radionuclide, radioactive contamination, effective dose*

INTRODUCTION

2016 marks 30 years since the major accident in the history of nuclear power plants (active zone melting and thermal explosion) that took place on 26th April 1986 at 4th reactor of Chernobyl Nuclear Power Plant (Ukraine). Emissions of radio nuclides were particularly high and affected many countries in Europe, including our country. The 4 reactors in operation at the time run on natural uranium (U-238) with low-enriched U-235, a high producer of Pu-239 (strategic material for nuclear weapons).

Although this type of reactor was well known by the operating personnel, they conducted an experiment with the turbine running in the inertial mode and lowering reactor's power at 10%, but the return to full power (thousand MW) took only 2 seconds which led to a loss of control and the impossibility of an emergency shutdown of reactor no. 4. The rapid and uncontrolled increase in temperature of the reactor core produced two successive explosions seconds after each other that threw the 1000 tons concrete for protection, as well as large amounts of nuclear fuel with fission products and activation products, along with the burning graphite moderator [1].

Definitions of specific terms

1. Activity (radioactivity) of a radionuclide: the unit of work in the International System (S.I.), is one disintegration per second, or s-1, with the name Becquerel and symbol Bq. Curie - special name for the tolerated unit of the activity of a radionuclide, with the symbol Ci; is 3.7 x 1010 disintegrations per second

---

[1] Romanian Society for Radiological Protection, Bucharest

(approximate activity of radon – 222 in equilibrium with one gram of radium – 226) and respectively 3.7 x 1010 Bq.

2. Half-life – the time after which the number of nuclei of a radionuclide is reduced to half by radioactive decay with symbol T1/2, or Tf is used.

The biological half-life – the time required for a biological system to remove half of the nuclei (stable or radioactive) by metabolic processes with symbol Tb. The effective half-life – the time needed to halve the number of radioactive nuclei (activity) by decay and metabolic processes with Tef symbol.

3. Effective dose – weighted sum of equivalent doses from external and internal exposure, performed on all organs (tissues) of the body (the absorbed dose multiplied by the weighting factor of radiation and weighting factor of tissue or organ). In the S.I. unit is J/kg with the name Sievert and symbol Sv.

The effective dose limit for occupationally exposed workers – effective dose limit for people working in environmental radiation is 20 mSv per year. The effective dose limit for the population – effective dose limit for an individual in the population is 1 mSv per year.

CONTAMINATION OF THE ENVIRONMENT

Fission products (Cs-137, Sr-90, Sr-89, I-131, etc.) and activation products (Cs-134, Co-60, Fe-55, Fe-59, etc.) were released in atmosphere and transported by air currents throughout the northern hemisphere. The most affected (radioactive contamination) were Belarus, Ukraine and European Russia; less contaminated air currents reached many other countries in NW Europe (mainly Norway, Sweden, Finland), and to S and S-V Europe, inclusively to Romania.

Rainfall and dry deposition made possible contamination of the environment (soil, surface and biosphere).

Cs-137 was the easiest to detect (beta-emitting and gamma-emitting radiation) and has a great half-life period (Tf or 1/2) of approximately 30 years, for which most of the estimations of environmental and human contamination reported to this radionuclide.

Table 1: Surfaces contaminated with Cs-137 in some countries affected by the Chernobyl nuclear accident [2]

Country*)	**37-185 (kBq/m^2)**	**185-1480 (kBq/m^2)**	**over 1480 (kBq/m^2)**
Russia	49800	7800	300
Belarus	29900	14400	2200
Ukraine	37200	4100	600
Sweden	12000	-	-
Finland	11500	-	-
Norway	5200	-	-
Austria	8600	-	-
Bulgaria	4800	-	-
Switzerland	1300	-	-
Greece	1200	-	-
Slovenia	300	-	-
Moldavia	60	-	-

*) In Romania, most of the surface was contaminated with Cs-137 with values below 2 kBq/m^2. There were large areas contaminated 2-10 kBq/ m^2 in Oltenia, Banat, N-E Moldova, central and northern Muntenia; here they were found locations with contamination exceeding 10 kBq/ m^2.

ASPECTS OF RADIATION PROTECTION IN ROMANIA

Monitoring environmental radioactivity and food radioactivity in Romania [1,3] was carried out by:

- 47 Environmental Radioactivity Monitoring Stations (belonging to the former National Council for Water, today 37 stations form the National Network of Environmental Radioactivity Monitoring and belongs to the Ministry of Environment)
- 22 Ionizing Radiation Hygiene Laboratories, of which 4 were from the Institute of Hygiene and Public Health in Bucharest, Iasi, Cluj and Timişoara (Ministry of Health)
- departamental laboratories (Institute of Atomic Physics – IFA Măgurele – Bucharest, Institute of Nuclear Energy Reactors – IRNE Pitești, Ministry of National Defense – MND, etc) (The Laboratory for radiochemistry of the Military Center for Medical Research also had tasks of human and environmental radioactivity monitoring in addition to the experimental research. There was also a laboratory to

measure the radioactive contamination of man (with whole body counter).

In the period immediately after the accident (the night of April 30, 1986 when contaminated air masses came first in the N-E) and in the years after the accident the following analyzes were performed:

- global beta measuring and gamma spectrometry of aerosol filters, total atmospheric deposition, surface and drinking water analysis, soil, wild vegetation and crops analysis, animal products and food menus from various canteens in Bucharest and in the country analysis
- direct measurement of radionuclides incorporated into man (I-131, Cs-137 and Cs-134) with MND and IFA whole body counter
- radiation dose exposure estimation for humans.

Among the measures taken for radiation protection of population in Romania, it is worth mentioning:
- consumer restrictions on certain foods (dairy products contaminated with I-131, Cs-137 and Cs-134) based on the values determined by measuring the radioactivity of food in the most contaminated counties
- forbidding sport events scheduled to take place outdoors on May 2
- administration of stable iodine for children, beginning with 3th May

Recommendations:
- extensive washing of vegetables before consumption
- reduced time spent in the open in the first week after the accident.

Negative aspects concerning the application of radiation protection measures:

- insufficient public information on the accident,
- KI administration started with a two days delay leading to reduced performance at about 50% and the administration was not performed at all children in areas contaminated with I-131.

ENVIRONMENTAL, FOOD AND HUMAN CONTAMINATION IN ROMANIA

After corroborating the results of radioactivity monitoring of the environmental factors, water and food, it was possible to create a map of radioactive fallout in our country in three stages: 1st to 2nd of May, 3rd - 4th of May and 5th to 6th of May respectively. So, the greatest contamination occurred due to the fallout of 3rd to 4th of May, which came from N-E and followed the Eastern and Southern Carpathians, with the southern area being the most contaminated (Figure 1) [4].

In atmospheric aerosols there were readings of a maximum of 103 Bq/m^3 for I-131, respectively 63 Bq/m^3 for Cs-137 at Toaca station in Ceahlău on 1st of May 1986; also readings of 17 Bq/m^3 I-131 and 14 Bq/m^3 for Cs-137 at Fundata station (Braşov county). These peaks declined rapidly in the second half of May and early June 1986, going as low as a 1000 times lower. Regarding the average concentration of Cs-137 in the aerosols, from about 106 Bq.s/m^3 in 1986 fell below 105 in 1987 and in 1991 it went back to the value from before the accident (about 200 Bq.s/m^3) [4,5].

Atmospheric radioactive depositions values were in 1986 over 3 orders of magnitude higher compared to before Chernobyl accident. As late as 1993 the average values of Cs-137 deposition reach 1 order of magnitude over that of 1985 because of wind carrying out the contaminated dust and returning in the form of radioactive fallout.

Average concentrations of Cs-137 in untilled soil samples were of 350 Bq/kg, with peaks in excess of 1000 Bq/kg in the northern county of Gorj. High levels of Cs-137 in untilled soil were recorded at Toaca-Ceahlău, Targu Mures, Gheorghieni and Parâng, with maximum levels of 2050 Bq/kg of dry soil.

In surface water, high values of Cs-137 were determined 2 or 3 days later than the atmospheric reading, measuring 50 Bq/m^3, with rapid drop below 10 Bq/m^3 in 1987 and 1988, returning to the values from 1985 as late as 1993.

The contamination of wild vegetation was carried out by fine radioactive particle deposition and measuring average values of Cs-137 as high as 1000 Bq/kg of dry vegetation, with values declining to before the accident in 1990. Contamination of crops by absorbing radionuclides in the soil was quite low, so radionuclide values decreased rapidly in the coming years [3].

The highest level of contamination with I-131 in food was found in ewe`s milk, with values of about 1300 Bq/L or higher, which led to temporary restriction in consumption imposed by the Ministry of Health, for dairy products. Cs-137 values in milk and dairy products were about 500 Bq/kg (Table 2). This radionuclide content in food has decreased since 1990, and since 2000 has reached the 1985 values.

Three stages of contamination in Romania: 🟥 1 – 2 🟨 3 – 4 🟦 5 – 6

Table 2: Content of Cs-137 (Bq/L or kg) in drinking water and foods [5, 6]

Food	1986	1987	1988 - 1991	2003
Water	-	0.05	0.002 – 0.009	0.002 – 0.009
Milk	10 - 200	27.92	1.02 – 5.13	0.01 – 0.137
Dairy products	10 - 500	61.98	5.07 – 16.61	-
Meet	50 - 300	47.50	1.31 – 39.25	0.014 – 10.28
Meet products	10 - 727	23.19	1.50 – 19.15	-
Grain products	50 - 100	42.16	1.01 – 12.15	0,251
Fruits and vegetables	7 - 411	46.43	1.89 – 23.39	0.037 – 0.265
Food menu/24 hours	-	23.69	1.50 – 4.49	-

If immediately after accident experts paid particular attention to radionuclides I-131 and Cs-137, easily determined by gamma spectrometry directly from samples, by the end of the year and in following years measurements were performed to determine the content of Sr-90 in water and food. Aerosols contamination levels with Sr-90 were less than 1/10 the levels of Cs-137 so the food contamination with Sr-90 was much lower, generally below 10 Bq/kg or L of product (Table 3).

Radionuclides Cs-137, Cs-134 and Sr-90, a little transferable from soil to plant, however they were detected many years after the accident; radioactive contents fell sharply in 1987 and then steadily, currently reaching in most foods well below 1 Bq/kg, hard to detect even with radiochemical analysis. There still are very low values for Cs-137 (units Bq/kg) in berries, mushrooms and wild venison.

Table 3: Content of Sr-90 (Bq/L or kg) in drinking water and foods [5, 6]

Food	1987	1988 - 1991	2003
Water	0.04	0.003 – 0.010	0.001 – 0.066
Milk	0.43	0.14 – 0.33	0.068 – 0.930
Dairy products	0.75	0.19 – 0.76	-
Meet	0.46	0.10 – 0.24	0.087 – 0.690
Meet products	0,62	0.09 – 0.20	-
Grain products	0.70	0.25 – 0.76	0.135 – 0.730
Fruits and vegetables	0.97	0.10 – 0.98	0.047 – 1.060
Food menu/24 hours	2.30	0.19 – 0.23	-

Assessment of human internal contamination with radionuclides I-131, Cs-137, Cs-134 and Sr-90 (Table 4) was performed both directly for the first three radionuclides (measuring radionuclides from humans) and by estimating the contamination based on the values of radioactive content determined in drinking water, food, and in real or hypothetical food menu (Table 2).

Table 4: Content of Cs-137, Cs-134 and Sr-90 in the human body (direct measurement/ estimation from ingestion of food) in Romania [6]

Radionuclide		1986	1987	1988	1989	1990	1991	1992	1993
Cs-137	measurement	1000 - 2000	2000 - 2500	800 - 1700	500 - 1100	300 - 500	< 300	< 300	< 300
	estimation	1538 - 20383	2335 - 12774	415 - 673	106 - 198	82 - 150	80 - 140	60 - 119	19 - 38
Cs-134	estimation	686 - 8703	729 - 4894	94 - 153	18 - 33	10 - 18	5 - 10	1 - 3	-
Sr-90	estimation	30 - 100	18 - 57	12 - 38	12 - 34	11 - 32	10 - 30	9 - 28	8 - 25

After about 80 days I-131 disappeared from humans and food through physical decay (if 10 Tf pass, it is considered that radionuclide decreases in values too difficult to determine; Tf for I-131 is 8.1 days). In terms of I-131 content found in thyroid, it presents very different values to a few thousand Bq only in May and June, depending on the level of contamination of the studied area and the food consumed. These rates were still much lower compared to human radioactivity/radiation dose received in the case of thyroid scintigraphy (tens - hundreds of kBq) [1,6].

For humans, Cs-137 + Cs-134, from about 2500 Bq in 1986 the values have gradually decreased to a point where after four years they went below 300 Bq. The loss of activity of the two radionuclides in humans was attributed to their reduction in food and to metabolic processes in the human body (Tb for the two radionuclides is 100-150 days) or by disintegration for Cs-134 (Tf = 2.05 years); so that after 1990 the Cs-137 values fell below the detection limit of the equipment used for the direct measurement. Sr-90 contamination for humans was much lower, estimated values below 100 Bq (radionuclide emits only beta radiation that can only be detected in small biological samples and the low contamination of foods did not allowed measuring this radionuclide in humans) [1,6].

ESTIMATION OF THE EXPOSURE DOSE FOR THE POPULATION OF ROMANIA

Immediately after the accident, Oncescu and Galeriu (IFA Bucharest – Măgurele) have calculated the exposure dose due to radioactive contamination of the population in our country which calculated to be about 1 mSv for the first year after the accident. Values are similar to those published by WHO (World's Health Organization) and IAEA (International Atomic Energy Agency) for other European countries (Finland: 0.44 mSv, Germany: 0.5 to 1.1 mSv, Italy: 0.61 mSv, Poland: 0.95 mSv, Switzerland: 1 3 mSv etc.) [1].

The subsequent calculation of the effective dose received by man from radionuclides determined in air, water and food for the most contaminated areas in Romania, except the contribution of I-131, resulted in average values close to 1 mSv in the first year after the accident, with a greater fall in 1988 (the greatest contribution to contamination was from Cs-137 and Cs-134 in food). Between 1990 and 2000 and now, the annual effective dose for humans fell below 50 µSv, values over 40 times lower than the dose received by humans from background radiation [4].

Figure 2: Exposure assessment of Romania's population – dose reconstruction by food based on Cs-137 concentration in atmospheric deposition [4, 5]. Minimum exposure dose of 0.2 mSv in Satu Mare County, maximum exposure dose of 2.1 mSv in Gorj County.

Doses of radiation exposure of the population in Romania after the nuclear accident vary by an order of magnitude between 0.2 and 2.1 mSv in the first year (Figure 2), based on contaminated air masses movement (Figure 1) as well as wet and dry deposition in our country. Thus, there were areas (counties) with quite small exposure doses, less than 0.5 mSv such as Satu Mare, Salaj, Maramures, Sibiu, Brasov, Harghita, while in other counties exposure doses were even over 1 mSv such as: Caras-Severin, Gorj, Mehedinți, Tulcea, Neamt, Vrancea, Teleorman.

The average dose received by most of the European countries of about 1 mSv is incomparably lower than that of more than 10 mSv received by population in heavily radioactive contaminated areas of Belarus, Ukraine and Russia. This dose of about 1 mSv in the first year after the accident is below the natural background exposure (irradiation) had a low radiological significance on health.

Natural background radiation exposure (cosmic radiation, earth radiation given by natural radionuclides present in the environment, food and humans) is about 2.4 mSv per year for the entire planet, with the exception of areas with high natural background radiation (even more than 20 mSv per year in some areas of India, Brazil, Congo, Sweden) due to the massive presence of natural radionuclides [1].

Thus, the additional exposure dose received by most of the population of Europe in 1986 was about half of the natural background exposure, which is a quite low dose, closely to effective dose limit (of 1 mSv per year) supported by legislation for an individual of the population. To be mentioned that the effective dose limit allowed for workers exposed for professional reasons (who work with ionizing radiation in the environment) is 20 mSv per year.

Given the levels of radioactive contamination of the environment in Romania, much lower in comparison with Ukraine, Belarus and Russia, the exposure doses received by our population were relatively low (0.2 to 2.1 mSv in 1986) well below those that could produce significant biological effects on human health. Moreover, studies carried out by the hygiene institutes of Romania did not reveal an increased incidence of congenital malformations in children born between 01.10.1986 and 31.12.1987 compared with the reference group (those born before 1986) [3].

Exposure doses and biological effects post-Chernobyl [2]

Average exposure doses received by the affected people in Ukraine following the nuclear accident were distributed as follows:

- 100 mSv, about 240 000 people participating in decommissioning the damaged reactor
- 30 mSv, about 116 000 people evacuated,
- 10 mSv, tens of thousands of people that continued living in contaminated areas, in the first years after the accident.

It is estimated that the maximum exposure dose can be even with an order of magnitude higher in some areas with massive radioactive contamination from the three countries Belarus, Russia and Ukraine.

In other European countries, the maximum dose was about 1 mSv in the first year after the accident, with a progressive decrease in the coming years. The dose is well below the natural background exposure (irradiation) has a low radiological significance.

Another 200,000 workers who received doses of 0.01 to 0.5 Sv were at increased risk of developing late effects, including cancer that could put their lives in danger.

Of the 600 workers that participated directly in the decommissioning, 134 received doses of 0.7 and 13.4 Sv and develop radiation sickness (ARS – Acute radiation syndrome). Of these, 30 died shortly after the accident [2].

In areas heavily contaminated in the three countries, measures taken to limit radiation exposure have changed the lives of millions of people (returning to homeland, modification of eating habits, restrictions and job changing) to damage health conditions including psychiatric problems.

Thyroid cancer was given particular attention, about 1800 cases for exposed children, which greatly exceeds estimates in the 1986. The cases of leukemia (latency 2-10 years) weren't significantly higher in staff directly involved in decommissioning. The greatest increase in cases of thyroid cancer for children has been reported in the Gomel region of Belarus (near Chernobyl) [7].

In the most contaminated areas of Russia, Belarus and Ukraine there are still values of Cs-137 and Sr-90 easily detectable in water and food; thus, in the Bryansk region (Russia), Cs-137 had values of 90 kBq/kg in predatory fish meat, high value for humans too, up to 50 kBq, which led to estimation of doses ranging up to 1.8 mSv in 1996. These values are well above those detected in Romania immediately after the accident [2].

Ever since 1987, a special monitoring program of about 7 million people affected by the accident has begun: liquidators of consequences of the accident (1986 - 1987), evacuated population in 1986 and established in other areas of the former USSR, residents of areas heavily contaminated with Cs -137, Sr-90 and Pu-239, descendants of the irradiated persons (liquidators, people evacuated), people contaminated with I-131, aged 0 to 18 years during the accident [7].

Epidemiological studies have revealed: an increase in the number of people with psychological problems, number of suicides and overall violent deaths among liquidators and evacuated population due to insufficient information on the effects of ionizing radiation, social dislocation and diminishing quality of life. Only complete epidemiological studies will halt the trend of attribution of increasing incidence of all cancers exclusively to the effects of the nuclear disaster, especially in areas heavily radioactive contaminated [8].

CONCLUSIONS FOR CONSEQUENCES OF THE CHERNOBYL ACCIDENT IN ROMANIA

1. The level of radioactive contamination of the environment in Romania after the nuclear accident in 1986 was relatively similar to that of other central and eastern European states; 10 kBq/m^2 at ground level, with few areas over this value.

2. The main radionuclide contaminants, I-131, Cs-137, Cs-134, even Sr-90 from deposition and aerosols immediately after the accident passed quickly in plants and animals. I-131 showed values close to 1 kBq/kg, Cs-137 and Cs-134 values of several hundred Bq/kg, whereas the Sr-90 was below 10 Bq/kg.

3. Radionuclides Cs-137, Cs-134 and Sr-90 transfer difficult from soil to plants trough absorption, were still detectable in food many years after the accident; radioactive contents fell sharply in 1987 and then steadily, reaching below 1 Bq/kg between 1990 and 2003 in most foods. At the same time, there were somewhat higher values detected in berries, mushrooms and venison.

4. In humans, Cs-137 from 1000 to 2000 Bq gradually decreased, so in 1990 reached about 300 Bq. The annual effective dose decreased from about 1 mSv in the first year after the accident, to below 50 µSv between 1990 and 2000, respectively below 10 µSv between 2000 and 2010.

5. Besides the three heavily radioactive contaminated states (Belarus, Ukraine and eastern Russia), other contaminated European countries reported no biological effects on the population after the accident.

Using direct anticoagulants (DOACs) in cancer and other high-risk populations

Cristina Vârlan[1], Florina Topliceanu[1], Lavinia Bârsan[1], Eduard Dănăilă[1], Mihai Șotcan[1]

Abstract: *The major practical advantage of the direct oral anticoagulants (DOACs), comprising the thrombin inhibitor dabigatran and the factor Xa inhibitors apixaban, edoxaban, and rivaroxaban, over vitamin K antagonists is their fixed dosing without the need for laboratory monitoring. With the recent, rapid introduction of the DOACs for the treatment of acute venous thromboembolism (VTE), clinicians are now faced with various questions regarding the efficacy and safety of these compounds overall and in specific high-risk populations. The collective evidence from 6 large clinical trials involving 27,000 patients has demonstrated that DOACs are as effective as vitamin K antagonists (VKA) in preventing recurrent VTE while being associated with a significantly lower risk of major bleeding. These findings are consistent in subgroups of patients with pulmonary embolism, the elderly, and those patients with a high body weight or moderate renal insufficiency, making these agents suitable for a broad spectrum of patients with VTE. DOACs are also an attractive treatment option in patients with VTE and concomitant cancer, thrombotic antiphospholipid syndrome, or heparin-induced thrombocytopenia, but the currently available clinical data is insufficient to make evidence-based recommendations on the use of DOACs in these settings. Several studies evaluating the efficacy and the safety of DOACs in these high-risk populations are underway.*

BACKGROUND

Anticoagulant treatment of thrombotic conditions dates back to the 1930s and 1940s when unfractionated heparin (UFH) and vitamin K antagonists (VKA) were the first drugs to become available. They proved to be effective in preventing death in patients with venous thromboembolism (VTE), comprising deep vein thrombosis (DVT) and pulmonary embolism (PE), and remained the mainstay of anticoagulant therapy in the decades thereafter. The introduction of low-molecular-weight heparin (LMWH) in the 1980s marked the next breakthrough. These drugs could be injected subcutaneously in fixed doses, which simplified the initial management of acute VTE greatly and opened up the opportunity to treat these patients at home. From that time on, a treatment regimen of initial LMWH followed by long-term VKA for at least 3 months was considered standard of care for patients with VTE.

Recently, within a time span of nearly 4 years, the thrombin inhibitor dabigatran [1] and the factor Xa inhibitors apixaban, edoxaban, and rivaroxaban [2,3] collectively termed direct oral anticoagulants (DOACs), were compared with conventional therapy for

---

[1] Carol Davila University Emergency Military Hospital, Bucharest, Romania

treatment of acute VTE in several large clinical trials. Now that these agents have been approved by the respective regulatory agencies around the world, physicians yet have another treatment option for their patients with VTE. This contemporary DOAC revolution has led to a quickly changing landscape of antithrombotic treatment. Clinicians are faced with various clinical questions regarding the efficacy and safety of these drugs overall and in subgroups of high-risk patients. Therefore, in the present review, we briefly discuss the collective evidence from the phase 3 clinical trials evaluating DOACs for VTE treatment. In addition, we will assess the potential role of DOACs in patients with cancer, the antiphospholipid syndrome (APS), or heparin-induced thrombocytopenia (HIT).

METHODS OF DOAC TRIALS IN THE SETTING OF ACUTE VTE

More than 27,000 patients were enrolled in several randomized clinical trials that compared the efficacy and safety of either one of the DOACs with VKA therapy targeted at INR of 2-3 in the treatment of acute, symptomatic DVT or PE. Importantly, the definitions of recurrent VTE and bleeding were similar across all studies and fallowed the recommendations of the International Society on Thrombosis and Hemostasis (ISTH). Outcome events in all trials were adjudicated by the same independent committee who was blinded for treatment allocation, resulting in a similar objective judgment of recurrent VTE and bleeding. Noteworthy differences between the trials are the use of an initial LMWH lead-in period of 5 days in patients receiving dabigatran or edoxaban, whereas apixaban and rivaroxaban where given as oral monotherapy, and the open-label design of the studies evaluating rivaroxaban opposed to the double-blinding in the other studies.

Recently, we reviewed and summarized the evidence from these phase 3 trials in a meta-analysis [4]. Using these data, we will answer clinically relevant questions to aid the physician in choosing the optimal treatment for his or her patient with VTE. Specifically, we will discuss the overall efficacy and safety of DOACs compared with VKA, differences between dabigatran and the factor Xa inhibitors, and the efficacy and safety of DOACs in high-risk subgroups of patients with PE, elderly patients, obese patients, and patients with moderate renal impairment.

CLINICAL QUESTIONS REGARDING THE EFFICACY AND SAFETY OF DOACS FOR VTE TREATMENT OVERALL AND IN HIGH-RISK SUBGROUPS

Clinical question 1: what is the overall efficacy and safety of DOACs in the treatment of acute symptomatic VTE compared to VKAs?

The main finding of the aforementioned meta-analysis was that DOACs are as effective as VKA in preventing recurrent VTE. Because all trials were designed to demonstrate non-inferiority of DOACs, this should reassure the clinician of the overall efficacy of these agents. Most importantly, the comparable efficacy observed in DOAC recipients was paralleled by a 40% relative reduction in major bleeding compared with VKA. Consistent with this substantial reduction in major bleeding, DOACs were associated with a significant 60% relative reduction in the incidences of intracranial and fatal bleeding, the most feared components of major bleeding. In line with the reductions in major bleeding, patients on DOACs had a 25% lower relative risk of experiencing clinically relevant non-major (CRNM) bleeding. Of note, no significant difference in the incidence of major gastrointestinal bleeding between DOACs and VKA was observed, unlike earlier reports raising concerns on an increased risk of gastrointestinal bleeding in patients on DOACs. In support of this finding, a recent population-based study confirmed a similar risk of gastrointestinal bleeding associated with DOACs compared with VKA in non-atrial fibrillation patients [5].

Clinical question 2: are there any differences between the factor Xa inhibitors and thrombin inhibitors with respect to efficacy and safety?

Although the result of the studies evaluating oral direct thrombin and factor Xa inhibitors are frequently combined, in fact they are two distinct drug classes with important pharmacokinetic and pharmacodynamic differences. Compared to oral factor Xa inhibitors, dabigatran has a lower bioavailability requiring administration as a prodrug, has a longer half-life, and is more dependent on renal clearance. Dabigatran is not hepatic metabolized by the P450 cytochrome system and could therefore be a treatment option in patients with liver disease. In contrast, factor Xa inhibitors undergo significant CYP3A4 metabolism and thus are contraindicated in patients with significant liver impairment. Of note, also among the factor Xa inhibitors there are some differences in pharmacologic properties. Clinicians should take these drug characteristics into account when choosing the DOAC that best suits their individual patient, but they also want to know whether there are any important differential effects between these two classes of DOACs in terms of efficacy and safety. Overall, these are no significant differences in efficacy and safety between dabigatran and factor Xa inhibitors. Hence, the choice for a specific DOAC should primarily be based on drug characteristics (eg, renal clearance), treatment regimen (eg, once vs twice daily dosing), and preference for a LMWH lead-in rather than the efficacy or safety profile.

Clinical question 3: can I prescribe DOACs also to high-risk patients including those with PE, body weight>100 kg, the elderly (ie, age≥75 years), or a moderate renal insufficiency?

The overall favorable efficacy and safety of DOACs in the setting of VTE compared with VKA is reassuring and justifies their use in the general population. However, not all clinicians are confident in prescribing these drugs in specific subgroups of high-risk patients. They may have questions regarding the efficacy of DOACs in patients presenting with PE, have concerns that patients with a high body weight will not reach sufficient drug blood levels putting them in risk of recurrent VTE, and fear that the risk of DOAC-related major bleeding complications may be higher in elderly patients, as well as in those with moderate renal insufficiency given the partial renal clearance of DOACs. The similar efficacy of DOACs compared to VKA is consistent in patients presenting with PE, patients with a body weight >100 kg, patients aged 75 years or older, and patients with a creatinine clearance between 30 and 50 mL/min. Moreover, the overall significant reduction in major bleeding associated with DOACs is maintained in the subgroups of elderly patients and patients with moderate renal insufficiency. Based on these results, DOACs should be considered to be an appropriate treatment option for acute VTE in a broad spectrum of patients.

OTHER HIGH-RISK POPULATIONS WITH VTE

Clinical question 4: are DOACs suited for my cancer patients with VTE?

It is estimated that 20% of all VTE are related to cancer and anticoagulant treatment in these vulnerable patients is often challenging. Cancer patients with VTE are at increased risk of developing recurrent VTE compared to non-cancer patients, but also have a higher risk of major bleeding. LMWH is currently recommended over VKA for treatment of cancer-associated VTE due to its better efficacy in preventing recurrent VTE with a similar risk of bleeding compared to VKA.[6] However, LMWH therapy may be burdensome, particularly in cancer patients that often require indefinite anticoagulant treatment. Because DOACs offer a simple oral treatment regimen without the need for anticoagulant control, they could be an attractive alternative. However, at present, clinicians should refrain from providing these drugs to cancer patients since they have not been compared directly to LMWH. Other concerns are possible drug-drug interactions with antineoplastic agents, in particular P-glycoprotein inhibitors, and the gastrointestinal absorption of DOACs in vomiting cancer patients or those with chemotherapy-induced intestinal mucosal defects. Nevertheless, the subgroup analysis of the 1,500 cancer patients enrolled in the DOAC trials does provide guidance for those situations when LMWH is not an option, for instance when patients are unable or unwilling to take daily subcutaneous injections. Interestingly, in these patients, a possibly better efficacy of DOACs compared with VKAs without an increased risk of major bleeding was observed.[4] It should however be realized that cancer patients in the trials probably had a favorable cancer prognosis compared to the real-world cancer population. Patients with a limited life expectancy were excluded from the trials, as were patients in whom long-term VTE treatment with LMWH was anticipated.

Recently, the pooled results of the subgroup of cancer patients enrolled in the trials comparing dabigatran with VKA was reported providing information on the characteristics of these patients as well as on cancer-prognostic data.[7] Active cancer was defined as cancer within 5 years prior to the VTE diagnosis. Compared with non-cancer patients, the 221 patients were older and had a lower renal clearance. The time spent within the therapeutic INR range of 2-3 was comparable between VKA-treated cancer and non-cancer patients (54.5% and 58.3%, respectively) which is higher than in the CLOT17 (46%) and CATCH (47%) trials. The most prevalent tumor types were prostate, colorectal, and breast cancer and 13% had metastasis. During 6 months follow-up, no significant differences were observed between dabigatran and VKA with respect to recurrent VTE or major bleeding. Detailed results of the cancer subgroups from the studies evaluating apixaban and edoxaban are expected shortly.

Before DOACs become an accepted treatment option for cancer-associated VTE, they have to be evaluated in a head-to-head comparison with LMWH. To this end, an important study comparing the efficacy and safety of edoxaban to LMWH in the setting of cancer-associated VTE has recently been started. One thousand patients will be randomized and followed for the occurrence of one of the components of the combined primary outcome of recurrent VTE or major bleeding. Following observations of a similar risk of recurrent VTE in patients with active cancer and those with a history of cancer, patients with VTE will be allowed to enter the study wither with active cancer or cancer treated within 2 years prior to the VTE diagnosis. Moreover, incidentally detected lower extremity DVT or PE are allowed as an entry diagnosis because treatment and outcome is similar for this group of patients. A last innovative feature of the study is the follow-up time of 12 months, which will provide valuable data regarding the treatment of patients with VTE and cancer beyond 6 months.

In conclusion, DOACs may become an attractive treatment for cancer-associated VTE, but at present LMWH remains the preferred option. Although the results of the trial population with cancer are encouraging, further clinical studies are needed to evaluate the efficacy and safety of DOACs directly against LMWH in this population.

Clinical question 5: can I treat my patients with thrombosis and the antiphospholipid syndrome with a DOAC?

APS is an autoimmune disorder characterized by arterial or venous thrombosis or pregnancy complications in patients who repeatedly test positive for circulating antiphospholipid antibodies (aPLA), i.e. lupus anticoagulant, anti-β2-glycoprotein-1 antibodies, or anti-cardiolipin antibodies. It is estimated that 10% of all patients with VTE have circulating aPLA and these patients are at increased risk of recurrent VTE compared to VTE patients without aPLA. When patients test positive for all three types of aPLA, the risk of on-treatment recurrence is as high as 25% over 5 years. The treatment of thrombotic APS is similar to the treatment of VTE in the general population (VKA targeted at an INR of 2 to 3), but is often extended indefinitely in case of persisting aPLA.

Now that DOACs are increasingly used for treatment of VTE, the question arises whether drugs are effective and safe for VTE treatment in the setting of APS too. From a patient perspective, DOACs may be a significant amelioration in this usually young population for whom lifelong anticoagulation with VKAs and frequent INR monitoring is not attractive [8]. Given that aPLA are prevalent in patients with VTE, the aforementioned DOAC trials in the setting of VTE must have enrolled patients with APS because this was not an exclusion criterion. However, patients were not routinely tested for aPLA and outcomes for the patients with known aPLA have not been reported. Therefore, the current knowledge of the efficacy and safety of DOACs for thrombotic APS is exclusively derived from case series and retrospective cohort studies. These represent a select population of thrombotic APS patients that were switched to a DOAC often because of labile INRs, bleeding on VKA, or logistic problems with INR monitoring.

In a retrospective multicenter cohort study, Noel et al [9] enrolled 26 DOAC-treated patients who had thrombotic APS for a median duration of 3 years. Seven patients had tested positive for all 3 types of aPLA and another 12 patients had lupus anticoagulant. Six of 26 patients received rivaroxaban or dabigatran as first-line treatment, whereas the others had been treated previously with another anticoagulant for 1 to 23 years. During a median follow-up of 1.5 years, 1 patient (3.8%) developed recurrent VTE and in 2 patients (7.7%) a bleeding event occurred that led to discontinuation of DOAC therapy.

However, other authors raised concerns about the effectiveness of DOACs to prevent recurrent APS-related VTE. Win and Rodgers [10] presented 3 thrombotic APS patients developing recurrent thrombosis 6-12 months following initiation of second-line DOAC treatment. The cause of these observations of DOAC-failures is unknown. The recurrence rate in APS patients is high and these failures may have otherwise developed under VKA therapy. Moreover, compliance may have been a contributing factor in these patients who were often switched to a DOAC due to difficulties with their INR control. Alternative explanations may be mechanisms intrinsically related to DOACs or their dosing regimens. For instance, inhibition of a single clotting factor might be insufficient to completely block the thrombotic potential in severe APS patients, or the short-life of DOACs causes the procoagulant stimulus to overcome the anticoagulant effect at trough levels.

In summary, current anecdotal evidence on the use of DOAC in thrombotic APS patients is conflicting. As a consequence, physicians should be careful with prescribing DOACs in these patients until robust data become available.

Clinical question 6: are DOACs a treatment option for preventing or treating thrombosis in patients with heparin-induced thrombocytopenia?

HIT is a complication of treatment with UFH or, less commonly, LMWH and is characterized by formation of antibodies to heparin-platelet factor 4 (PF4) complexes. These antibodies may trigger platelet activation in turn resulting in venous or arterial thrombosis, so-called HIT associated with thrombosis (HTT). A decrease in platelet counts is usually observed 5-10 days after initiation of heparin exposure. In patients with confirmed HIT, cessation of heparin therapy alone is not sufficient to prevent HITT and treatment with an alternative anticoagulant is required. Traditionally, 2 classes of anticoagulants have been used for the initial treatment of HIT: parenteral direct thrombin inhibitors, including argatroban, bivalirudin, and desirudin, and nonheparin antithrombin-dependent anticoagulants, including fondaparinux and danaparoid. Although these drugs are widely used in the treatment of HIT, they have several disadvantages ranging from high costs, low availability, need for drug monitoring, dependence on renal clearance, and the absence of an antidote. DOACs could potentially overcome all of these issues. The biochemical structure of DOACs has no similarities with heparin; hence, interactions with PF4 or heparin-PF4 antibodies are not to be expected. This has been confirmed in preclinical laboratory studies that demonstrated that rivaroxaban, dabigatran, and apixaban [13] do not cross-react with HIT antibodies and do not induce platelet activation in the presence of HIT antibodies. Hence, on theoretical grounds, these drugs could be used to treat HIT. These observations suggest that DOAC are a safe alternative to traditional HIT treatment, but confirmatory studies are needed.

In summary, the clinical experience with DOACs for HIT is currently limited, but they have the potential to become the mainstay of anticoagulant treatment in this setting. They do not interact with HIT antibodies and do not cause platelet activation in the presence of HIT antibodies. Together with their favorable pharmacokinetics, high availability, and lower costs, they could be particularly suited for patients with HIT. The results of the ongoing clinical study have to be awaited before the evidence-based use of DOACs in patients with HIT can be recommended.

CONCLUSIONS

With the recent introductions of the DOACs, clinicians now have multiple therapeutic options for oral treatment of patients with VTE. DOACs are as effective as VKA in preventing recurrent VTE, but are associated with a significant reduction in the risk of major bleeding and are easier to use with no need for dose adaptations. These findings in the general trial population are consistent with those in patients with PE, the elderly patients, heavy patients, and patients with moderate renal impairment, making DOACs a suitable treatment option for a broad spectrum of patients. Whether DOACs can also safely be used in patients with cancer-associated VTE, thrombotic APS, or HIT is currently not proven. Studies are underway to evaluate DOACs in these high-risk populations.

SYSTEMATIC REVIEW

Article received on May 10, 2016 and accepted for publishing on August 19 2016.

Risk factors and quality of life in late-life depressive disorders

Octavian Vasiliu[1], Daniel Vasile[1,2]

Abstract: *Late-life major depression is a high-incidence and difficult-to-treat affective disorder. Diagnosis of major depression in old age could also could be a challenge, due to aspects like (1) there is a higher vulnerability to the stigma of depression in this population, (2) hypochondriac ideation and somatic symptoms are the main symptoms, while depressive disposition or anhedonia are under-reported by such patients, (3) differential diagnosis includes various organic diseases, but also several psychiatric disorders, like neurocognitive disorders, organic affective disorders, drug induced affective disorders etc. Reduction of social relationships caused by retirement and loss of spouse and friends, as well as a decrease of personal income could precipitate or maintain depressive disorders during late-life. Quality of life in patients diagnosed with depressive major disorders is a rarely monitored parameter, although its importance for case management could not be overemphasized. A reduction of life quality correlates with a poorer functional prognosis, persistence of neglected residual symptoms, low adherence to treatment plan etc.*

Keywords: *late-life depression, geriatric depression, quality of life, risk factors, institutionalized population*

BACKGROUND

Late-life depressive disorders have a high impact over patients' quality of life, general well-being, risk of organic diseases recurrence, involvement in daily activities and life expectancy.

Although depression could be perceived as a part of normal process of ageing, this is only a relatively widespread misconception. Adjustment to changes in life style due to retirement, loss of the spouse, death of close friends, financial losses, decreasing of physical capacities etc, should not be confounded with major depressive disorder. Depression has been identified in 17-37% of elderly patients treated in primary care facilities, and 30% of these have a diagnosis of major depressive disorder [1].

Elderly patients are more sensitive to stigma associated with depression and this is a reason for them to declare less frequently than young adults that they have dispositional symptoms during epidemiological studies [2]. Therefore this kind of data should be regarded with caution, as an underestimation of the depression real incidence in late-life is very possible.

Table 1: Risk factors for depressive disorders in late-life population

Risk factor	Overall impact
Bereavement after loss of spouse, a child or other close relatives	Bereavement after a recent loss correlates with depressive symptoms in elderly [5] Elderly bereaved patients seek frequently medical help for their emotional discomfort [6] Most of the depressive symptoms are reported by mothers who have lost a child after a prolonged suffering and in fathers who lost a child by suicide; it's possible that old adults have a lower risk of depression caused by the death of a child than younger adults, possible due to better coping mechanisms [7]
Retirement	People who retired recently have a higher risk for depression than those who continued to work, although self-esteem scores didn't change significantly, as reported by a prospective evaluation during 2 years [8] Depressive symptoms increase when the retirement is sudden and perceived by the subject as being too early or forced [9] There is a reciprocal relationship, as patients diagnosed with depression tend to retire with 1.5 years earlier than those without depression [10]
Income decrease	Women who have lost their spouse have as main mediator of depression financial burden, while widowed males have mainly problems with house holding activities [11]
Interpersonal relationships decreasing	Loneliness was the only factor which correlated with depression scores in 8% of people aged 60-98 who were institutionalized, thus suggesting that loneliness is an independent risk factor for major depression [5]
Lower physical capacity	Old adults with sedentary lifestyle and physical disabilities had a higher risk (OR=2.44) for depressive symptoms appearance than those with good mobility and that were physically active, according to a 8 years follow-up study; the risk maintained high (OR=1.99) in those with low mobility but active life-style, when compared to those who were both physically active and have an intact mobility [12]
Somatic symptoms, pain included	Presence of several organic diseases predicts late-life depression [5] Organic pathologies which associate important pain have a risk for developing more depressive symptoms and a worsening of pre-existing depressive manifestations [13] Quality of life is decreased more in old adults with symptoms like physical pain, because this is associated with limitations in functionality, fatigue, sleep disturbances, depressive mood [14]
Physical or psychological symptoms of patient's spouse	There is a high correlation between depressive symptoms in both spouses: if one has depressive manifestations, there is a high risk for the other to have the same type of symptoms, and this correlation increases in frequency with the patients' age; age difference between spouses has been associated with more depressive symptoms, and those with younger spouses reported more depressive symptoms in 65+ age than spouses with minor age differences [15]
Psychological symptoms, including decrease in cognitive function	Elderly patients (60+) with major depression who have persistent insomnia have a 1.8-3.5 times higher probability to maintain depressive symptoms than those who doesn't have insomnia [16] Depression appears frequently in almost every type of neurocognitive disorder, even in mild cognitive disorder (MCI), and the risk for depression to increase the risk of MCI conversion to dementia is investigated [17] Late-life depression leads to further functional and cognitive decline [18]
Decrease autonomic functioning	Mobility deficits predict a higher risk of mortality and loss of autonomy in elderly patients [14]
Relocation in other area (from city to rural areas, or from his/her own residence into a long-term care facility)	Institutionalization, lower frequency of visits from friends or relatives and less involvement in social activities have been associated with greater risk for late-life depression [5] In institutionalized patients, depression is more common in women who were widow/single, younger or much older than the mean group age, with lower educational background, poor social and economic status, who live alone [20].

Detecting vulnerable populations for depression disorders is an important process if we look at the risk of early death from natural and unnatural causes in patients diagnosed with depressive disorder (71.1 vs. 75.9 years old) and loss of potentially years of life (13.4 vs. 10.2 years) comparative to the non-depressed population [3].

Risk factors for development of depressive disorder in late-life are intricate, with genetic vulnerability, cognitive diathesis, age-associated neurobiological changes, and stressful events, while protective factors are higher education, high socioeconomic status, and involvement in desired activities, inclusive of religious and spiritual nature [4].

Clinical manifestations of major depression in elderly patients has several peculiarities, like denial or dissimulation of feeling sad or anhedonia, but with predominance of somatic complaints, irritability and anxiety, self-isolation, low level of energy and slow movements.

OBJECTIVE

To assess the specific risk factors for late-life depression and to search for impact of this pathology over the patients quality of life, by analyzing data from literature.

Table 2: Quality of life in late-life depressive disorder

Lin J-H, Huang M-W, Wang D-W et al. [21]	Depressed elderly inpatients have less satisfaction and quality of life; female gender, duration of hospital stay, and in-hospital rehabilitation correlated significantly with quality of life scores.
Doraiswamy PM, Khan ZM, Donahue RM, Richard NE [22]	Late-life depression associates significant quality of life impairments in 5 out of 8 baseline SF-36 items; women rated their quality of life as worse than men on physical functioning and role physical; subjects aged over 70 reported lower quality of life on the summary physical component and a trend for higher scores on the mental component of the SF-36
Dombrovsky AY, Lenze EJ, Dew MA et al. [23]	All domains of health-related quality of life except physical functioning improved with successful acute and continuation treatment using paroxetine and/or monthly interpersonal psychotherapy
Hunkeler EM, Katon W, Tang L et al [24]	Collaborative care intervention (including depression care manager, primary care doctor, psychiatrist offering education, behavioral activation, antidepressants, a brief behavior based psychotherapy, relapse prevention geared to personal needs and preferences) was superior to usual care for depression in elderly patients (60+) diagnosed with major depressive disorder regarding quality of life, self-efficacy, satisfaction with care, remission of depression after 12 months
Heiligenstein JH, Ware JE Jr, Beusterien KM et al [25]	Treatment with fluoxetine for 6 weeks in patients over age 60, diagnosed with major depressive disorder, had improvements vs. placebo in all dimensions of SF-36 health status survey; before treatment these patients had lower values in mental health, role limitations due to emotional problems, social functioning, vitality, role limitations due to physical problems, bodily pain- as dimensions of quality of life and health-related dimensions.

METHODS

Main electronic databases (PubMED, EMBASE, CINAHL, Cochrane) were searched using as keywords „old age depression”, „late life depression”, „geriatric depression”, combined with „clinical dimensions”, „quality of life”, „risk factors”, „prognosis”, „evolution”.

All articles were analyzed, including clinical trials, systematic reviews, meta-analyses, case reports, case series, guidelines and editorials.

We formulated the following inclusion criteria for the selected papers: population age over 60; diagnosis of major depressive disorder, organic depression or mixed anxiety-depressive disorder; institutionalized or community dwelling residents; specified statistical method for data processing; risk factors and/or quality of life as specified variables.

Exclusion criteria were: unspecified age of studied population; age under 60; diagnosis of drug induced depressive disorders, or bipolar disorder- major depressive episodes.

RESULTS

According to the analysis of the data from literature, main risk factors for depressive disorders in elderly are illustrated in table 1. Each factor has a different impact over the onset or evolution of depressive symptoms, but these factors appear seldom isolated, therefore it is hard to quantify each variable's impact.

Patients diagnosed with depressive disorders in late-life have various risk factors for this affective disorder, like social events (d.e. retirement, lack of social interaction), psychologic aspects (d.e. bereavement, cognitive deficits) and organic diseases (d.e. somatic pathologies, decreasing of physical mobility). Therefore, it's important to configure a management plan that includes all these factors and adequate monitoring methods, in order to improve depressive symptoms severity, prognosis and risk of relapse.

Regarding the quality of life in depressed elderly patients, we found several studies which are presented in table 2. All the cited trials are randomized and included quality of life and/or health-related quantitative measurements as main or secondary variables.

Although only a small number of trials dedicated to evaluation of life quality in depressed elderly patients was found, we can conclude from the available data that (1) a significant correlation between depression and quality of life decrease was found; (2) treatment, either psychotherapy or pharmacotherapy, could help in resolving both depressive symptoms and alterations in quality of life; (3) several risk factors like female gender, duration of hospital stay, and in-hospital rehabilitation correlated significantly with quality of life scores.

CONCLUSIONS

There are many risk factors that could be correlated with the onset of a new depressive disorder in old age, or with a relapse or recurrence of a previously diagnosed major depression. Some of these risk factors could be corrected and thus patient's prognosis could be improved (d.e. symptoms related to organic comorbidities, like pain, dizziness, or medical aids for visual or hearing deficits), while others could be only monitored and assisted through counseling (d.e. reduced immobility due to untreatable or only partially treatable conditions, lower physical capacity or bereavement).

Quality of life is an important predictor of prognosis in depressive disorders and monitoring the patients' well-being should be more frequently recommended during psychopharmacologic or psychotherapeutic treatment in elderly population. An increased attention should be placed in patients with depressive disorders and risk factors for lower quality of life, like female gender or long duration of hospitalization.

Modern medicine has a new technology: Therapeutic electroporation

Lucia E. Ionescu[1], Diana M. Popescu[1], Gabriela V. Dumitrescu[1], Simona N. Bicheru[1], Marius Necșulescu[1], Viorel Ordeanu[1]

Abstract: *Electroporation is considered a new start-up in the treatment of various tumors; currently, researches are being conducted in order to develop this technology with medical applications. The technique consists in the significant increase in the electrical conductivity and permeability of the plasma membrane of cells resulting from the application of an external electric field. It is routinely used in molecular biology to transform bacteria, yeast, protoplasts and is performed using the electroporators. Currently, the process seems to be a real solution that enables a targeted drug to act with maximum efficiency on cells and tissues requiring treatment, resulting in obtaining a good therapeutic effect without major side effects. Therefore, pharmaceutical companies are trying to demonstrate through preclinical studies the potential efficacy of this technology, succeeding in recent years to achieve important steps in this direction.*

Keywords: *electroporation, therapy, tumor, medical application*

INTRODUCTION

Modern medicine is always looking for new technologies applicable to the diagnosis, prevention and treatment of diseases. Among these, the applications of molecular biology represent a direction of the future, particularly in the treatment of diseases currently considered incurable. Translational medicine applies the new discoveries, in molecular and genetic biology, as well as the techniques resulted from these, for therapeutics based on biology, which gradually replaces therapeutic based on chemistry. For example, by applying electric current at cell level, can be inserted into altered cells, the therapeutic molecules or transfection of genetic material can be achieved.

ELECTROPORATION

Electroporation is the electropermeabilization of cell membranes, which consists in increasing the electrical conductivity and permeability of the plasma membrane of cells, being caused by the application of an external electric field. This procedure is particularly useful in molecular biology in order to insert certain substances in a cell such as a molecular probe or a drug that can induce changes in cell functions or coding DNA [1].

Electroporation is a dynamic process that depends on local transmembrane voltage for each point at cell membrane level. For a certain type and duration of the

---

[1] Military Medical Research Center, Bucharest

pulse, there is a threshold of the transmembrane voltage in order to allow the expression of transmembrane electroporation phenomenon between 0.5 V and 1 V. This leads to defining threshold value of the magnitude of the electric field necessary to achieve the phenomenon of electroporation. Only the cells found in an electric field greater than the *threshold* value can be electroporated. If a second threshold is reached or exceeded, electroporation will compromise the viability of the cells, this phenomenon being called *irreversible electroporation* [2].

In molecular biology, the process of electroporation can be used to transform prokaryotic and eukaryotic cells. Bacteria that present a cell wall composed of peptidoglycans for protection, resistance and transport of substances are protected from environmental changes. Based on this characteristic, bringing the bacteria into contact with particular plasmids of interest may have the effect of transferring the plasmid to other bacterial cells, subsequent to an electroporation process by applying several hundred volts over a distance of a few millimeters. Subsequently, the cells must be handled carefully until they divide into new cells that contain new plasmids; this process is about ten times more efficient than chemical transformation [3].

This process is also highly efficient for the insertion of foreign genes in cell cultures and in particular in mammalian cell lines. For example, the process is used to produce *knock-out* mice (transgenic mice in which is inactivated a single target gene for the study of phenotypic characteristics encoded by this) as well as in tumor treatment, gene therapy, and cell-based therapy. The process for the insertion of foreign DNA molecules into eukaryotic cells is known as transfection. Electroporation is particularly effective for transfecting cells in suspension in a cultivation medium using an electroporation cuvette.

Electroporation has proven effective for use on *in vivo* tissues for *in utero* or *in ovo* transfection applications. The adherent cells to the substrate can also be transfected using electroporation, thereby providing an alternative to researchers for the trypsinization of the cells prior to transfection. Electroporation is performed using electroporators, purpose-built appliances which creates an electromagnetic field in the cell suspension, which is pipetted into a glass or plastic cuvette foreseen with two aluminum electrodes on its sides. For the electroporation of bacterial cells, a suspension of about 50 µl is used which, prior to electroporation, is brought into contact with the plasmid of interest. The mixture is pipetted in the cuvette, the voltage and the volume to be applied to the probe are set, and the cuvette is placed in the electroporator. Immediately after electroporation, 1 ml of liquid medium is added to the Eppendorf cuvette /tube and is incubated at a temperature which allows the multiplication of bacteria, to recover the cells and to express **antibiotic resistance**, followed by seeding on plates with nutrient agar.

For electroporation to be successful, the plasmid must be "*free of all salt*" because solutions with high concentration of sodium chloride can cause an electrical discharge (known as arcing), a phenomenon which often reduces cell viability.

For a more detailed investigation of the process, special attention should be given to the output impedance of the porator device and to the input impedance of the cell suspension (e.g. the salt content). Because the process requires direct electrical contact between the electrodes and the suspension, and it does not occur between isolated electrodes, it is obvious that the process requires the existence of electrolytic effects due to mild currents and electric fields [4].

Electroporators are special laboratory equipment that give the possibility to achieve electroporation for multiple samples at the same time, with sets of electrodes specific for cell cultures, such as X2HT Gemini system manufactured by BTX-Harvard. Electroporators can be set to different operating parameters, allowing researchers to optimize the electric field strength depending on the cell type and by the presence or absence of the cell wall [5].

Electroporators have been used on a wide range of cells, including *Escherichia coli* (for transformation) and mammalian cells (neurons, astrocytes, neuroglial, lymphocytes, monocytes, fibroblasts, epithelial and endothelial cells) from humans, mice, rats, and monkeys (for transfection [6].

Physical mechanisms of electroporation

Electroporation allows inserting into the cell DNA molecules, which do not have the ability to passively cross the cell membrane (the lipid hydrophobic bilayer). There are several ways in which changes can be caused to the electric field at the cell membrane level with very different mechanisms and effects. The electroporation advantage lies in the fact that lipid molecules are not altered in terms of chemical and the membrane has the ability to form a pore that will serve as a conductive path through the lipid bilayer [4].

Electroporation is a process with many stages and distinct phases [7]. Initially, a brief electrical pulse of 300-400 mV must be applied for less than 1 ms, which causes changes at membrane level related to the migration of ions in the surrounding solution. Once the critical stage is reached, a local rearrangement on the morphology of the lipids rapidly occurs and the resulting structure is considered to be a "pre-pore" because it is not a good conductor, but quickly leads to the formation of a conductive pore. Most evidence in support of this idea, come from the "flickering" process that occurs at the level of the pre-pores with the formation of hydrophobic regions of approximately 3Å [8].

If this theory is correct, the transition to the conductive pore may be explained by a rearrangement at the edge of the pores in which the lipid ends create a hydrophilic interface.

Finally, the conductive pores may suffer processes of reorganization, expansion or rupture, which can be influenced by various local factors such as the place and the moment in which the change occurs, the mechanical stress and the energy of the lipid bilayer existing at the time of trial [9].

MEDICAL APPLICATIONS

The optimization of electroporation is difficult to achieve, but it has been demonstrated that high voltage electroporation can almost irreversibly destroy the target cells, neighboring cells remaining unaffected. Thus, electroporation can form a new therapeutic approach in the treatment of cancer, cardiac disease and other pathological conditions which require the excision of tissue [10].

A recent technique called **non-thermal irreversible electroporation** has proved successful in the treatment of various types of tumors. This procedure involves the use of small electrodes (about 1 mm in diameter), placed inside or around the target tissue for applying short electrical pulses, repeating at a predetermined frequency and voltage, which increases resting transmembrane potential. As a result, when the applied electricity is higher than the threshold value for the target tissue, forming nanopores in the plasma membrane can become permanent and the cell repair mechanisms of “immortal” cancer cells become ineffective and the cells die.

The procedure is unique, due to the fact that compared to other tumor ablation techniques it does not affect the healthy tissue surrounding the tumor. In contrast, **reversible electroporation** occurs when electricity is applied through the electrodes below the threshold level of the electric field of the target tissue. Applying an electrical energy below the threshold allows the cells to rebuild the phospholipid bilayer and to resume normal operation. Reversible electroporation is carried out in the normal way for the administration of treatments which involve the insertion of some therapeutic molecules (drugs, genes, etc.) into cells. Since not all tissues have the same threshold of the electric field, precise calculations are needed before starting treatment, to ensure operating efficiency.

A major advantage of using non-thermal irreversible electroporation is that when done correctly, as a result of careful calculations made, it affects only the target tissue, while the proteins, the extracellular matrix and some critical structures such as blood vessels and nerves remain unaffected by this treatment. This allows a faster recovery and enables a faster replacement of the necrotic tumor cells with healthy cells. The first successful treatment of malignant skin tumors in mice was conducted in 2007 by a group of scientists (Garcia, Paulo A. & al.), who conducted the complete ablation of the tumor in 12 of 13 mice. They accomplished this by sending 80 pulses of 100 µsec to 0.3 Hz with an amplitude of the electric field of 2500 V / cm, to treat skin tumors. Prior to performing the procedure, the therapist must carefully calculate exactly what should be done and to customize the therapy to the patient needs using imaging (CT and MRI) to create an accurate three-dimensional image of the tumor. This information is very important because one can estimate the tumor volume and decide on the type of therapy, place and angle of insertion of electrodes and applied voltage, sometimes even during the procedure, especially when electroporation is used to treat brain tumors.

The whole procedure is quick (about 5 minutes); the success rate is high and therefore very promising for future treatment extrapolation to humans. A disadvantage would be that the released electricity can stimulate muscle cells causing their contraction, which in some cases can have serious or even fatal consequences. Therefore, a muscle relaxant agent (curare-like compounds) should be used while performing the procedure. The researches conducted so far have been successful, but the taken action must be subject to the existence of a risk when general anesthesia is being used. A recent technique called **irreversible high-frequency electroporation**, uses electrodes to apply bipolar electrical pulses at a high frequency, as opposed to low frequency monopolar electrical pulses. This type of procedure also leads to tumor ablation with the difference that it does not produce muscle contraction and therefore does not need a muscle relaxant agent [11].

Researchers have had success in treating the test animals with multiple tumor types. Even if you are not prepared to routinely apply this technique in the treatment of tumors in humans, non-thermal irreversible electroporation is used in practice for treating cutaneous and subcutaneous tumors. There have also been attempts to treat human cancer of the prostate, lung, kidney and liver. There are still many things to be set in place, on how to damage the animals and especially the man. Kenneth Thompson et al. tested the safety of applying this technique on humans who had tumors in their lungs, kidneys and liver. The treatment was found effective in 71% of cases and, respectively, in 49 patients out of the 69 cases of patients treated was achieved complete ablation of the tumor [12]. The highest rate of success was recorded in liver tumors. The result of this study thus provides encouraging evidence related to the future use of this technology as an alternative method of treating cancer in humans.

Electroporation can also be used for the insertion of drugs or genes into the target cell through the use of short, intense electrical pulses to transiently permeabilize the cell membrane. This procedure is referred to as **electrochemotherapy** when the molecules to be transported are represented by a chemotherapeutic agent or **gene electrotransfer** when the molecule to be transported is the genetic material (DNA) [4].

PHARMACEUTICAL APPLICATIONS

Some pharmaceutical companies have performed surveys on the development of electroporation procedures with the scope of providing a viable alternative to cellular uptake of drugs. This approach is based on the fact that human cells do not allow the free entry of foreign matter through the cell membrane, which results in delay in the operational efficiency of a drug. Therefore, electroporation can be a real solution to allow a drug to act directly, quickly and with maximum efficiency on cells and tissue requiring treatment, resulting in obtaining a good therapeutic effect without major side effects.

Therefore, Inovio and OncoSec tested the effectiveness of this technology and managed in 2013 to achieve important steps in this direction. The results allowed them to also achieve substantial gains: the company Inovio Pharmaceuticals (NYSEMKT: INO had gains of almost 500% and the company OncoSec Medical had gains of 150%. Inovio performs studies using synthetic vaccines, while OncoSec is testing therapeutic agents that are already used during cancer treatment. The company Inovio Pharmaceuticals has developed about 12 "*electroporation pipes*", for the treatment of cancer and infectious diseases. Thus, the tests performed on the H1N1 influenza vaccine developed by the company's specialists have highlighted the protective immune response comparable to conventional vaccines. Also, the SynCon DNA vaccine caused total protection against the infection with the viruses of Ebola and Marburg hemorrhagic fevers [13].

Preliminary studies for both types of vaccine, although in the initial stage, show that these exhibit a strong effect against the spread of these deadly viruses. On June 14th, 2014, Inovio announced that the H7N9 vaccine generated protective antibody HA with a percentage of 100% of the animals tested, and on July 10th, the results obtained from testing the HIV vaccine were published in the Journal of Infectious Diseases. Inovio found that the CELLECTRA system used for administering the Pennvax - B HIV vaccine improved the efficacy of the medicine in the first phase of testing. On July 18th, 2014 Inovio announced that electroporation significantly improves the outcomes of the DNA therapy in terms of stimulating the multiplication of blood elements. Administering with the CELLECTRA system the hTERT DNA vaccine used in cancer therapy and the anti-MERS vaccine has demonstrated that a good immune response has been generated during preclinical studies, improving the survival of patients [14]. OncoSec Medical conducted in preclinical testing centers studies for the treatment of metastatic melanoma, Merkel cell carcinoma (MCC) and cutaneous T cell lymphoma. In the study were included 15 patients with MCC, and so far the company's electroporation platform has been shown to be safe; in the last check, all patients showed an increase of IL-12 absorbing of at least 100 times, and in some cases up to 1,000 times.

This provides hope in regards to reducing the side effects that occur subsequent to immunotherapy. Also, studies have been conducted on a group of 25 melanoma patients. Were reported complete records for 21 of them and was observed that 38.1% had a favorable complete response lasting more than 6 months and in 61.1% of patients was observed a 30% regression of the tumor. All this led to an increase in the company's market share by 63%. It is considered that the near future will bring a series of novelties in this field, such as:

- the extension of the studies and obtaining positive results, for more than small populations of patients;

- reporting by Inovio of the data from the Phase 2 Study for VGX-3100 in the treatment of cervical dysplasia, which in Phase 1 has shown good immune response;

- reporting by OncoSec of the final data from the study of melanoma and for the Merkel cell carcinoma;

- presenting plans to launch a study for treating cutaneous lymphoma with T-cells, but also for the initiation of a new research for the treatment of solid tumors;

- OncoSec presenting the company's plans that expressly foresees combining the electroporation device with the anti-CTLA4, the anti-PD-1 and the anti-PD-L1. As is well known, the anti-PD-1s, particularly, was among the most frequently discussed cancer therapies last year, after Merck and Bristol-Myers have reported incredible data to the American Cancer Society (ASCO). All these led to the idea that electroporation increases the assimilation of some therapeutic agents and reduces side effects, thus making them even more efficient. Therefore, careful monitoring of therapy with anti-PD-1s and the OncoSec plans to expand the researches for the ImmunoPulse platform, finally pursue further researching for this therapeutic agent [15].

CONCLUSIONS

Therapeutic electroporation is a new treatment technology at cellular level. The method is based on the electroporation of the cell membrane which becomes selectively permeable to the therapeutic agents used. *In vitro* and *in silico* experiments are promising and have allowed the insertion of chemical or biological molecules in the target cells. The *in vivo* experiments on laboratory animals have given good therapeutic results, therefore, in the future may be applied to humans. Therapeutic electroporation can become in the near future, an important treatment for oncology, cardiac, infectious diseases etc., envisioning the predominant biological perspective of therapeutics in modern medicine.

The incidence of tracheoesophageal fistulas and it major determinant factors

Bogdan Petre[1], Ioana Oprea[1], Denisa Ghinescu[1], Mirela Bidilică[1], Ovidiu Bratu[1,2], Raluca Petre[3], Cristian Boroș[3], Narcis Tănase[1], Laurențiu Ene[1], Dan Corneci[1,2]

Abstract: *The tracheoesophageal fistula which occurred during oro-tracheal intubation of a patient in intensive care unit is a true challenge both in diagnostic and in therapeutic approach. The best treatment is prevention, by identifying risk factors but especially is important which the mechanism in the occurrence of tracheoesophageal fistula was. The occurrence of this complication in the evolution of hospitalized patients in ICU is accompanied by significant increase in mortality, contributing to negative prognostic. We have started a large multicentric study in April 2016 regarding all patients who required intubation longer than 7 days. The study will finish at the end of 2020. We are looking for a definite conclusion, in this moment we do not have enough data for a conclusion.[1, 2]*

INTRODUCTION

The tracheoesophageal fistula is an abnormal communication between the esophagus and trachea. It can be congenital or acquired. Most of them are congenital with a frequency of 1 to 3500/ 6000 births. In this case usually are associated, or appear within, with other birth defects (trisomy 13, 18 or 21, tetralogy of Fallot, other digestive problems or muscle skeletal VACTERL Syndrome (**V**ertebral anomalies, **A**nal atresia, **C**ardiac defects, **T**racheoesophageal fistula and/or **E**sophageal atresia, **R**enal & **R**adial anomalies and **L**imb defects.). Then, there are the malignant ones which appear in the posterior infiltrating tracheal wall or the anterior wall of the esophagus. The last ones are those acquired, non-malignant [1, 3, 4].

They occur particularly after a prolonged period of intubation with or without mechanical ventilation. Fistula can result from incidents of intubation maneuver, in the operating room but especially in ICU. The first fistula appeared after a prolonged period of intubation and was initially described in 1956 by d'Avignon [2, 4].

Several factors are involved in these serious complications during a prolonged period of intubation. The most important and most discussed about in recent years is represented by the cuff pressure of orotracheal tube. If the cuff is overinflated, it leads to compression on the rear wall membranous trachea, which in time leads to ischemia and necrosis, basically forming an abnormal communication between the trachea and esophagus. Other possible complication of a hyper-inflated cuff is tracheal stenosis or bleeding erosion of a significant blood vessel. Often, both situations can occur simultaneously. The

---

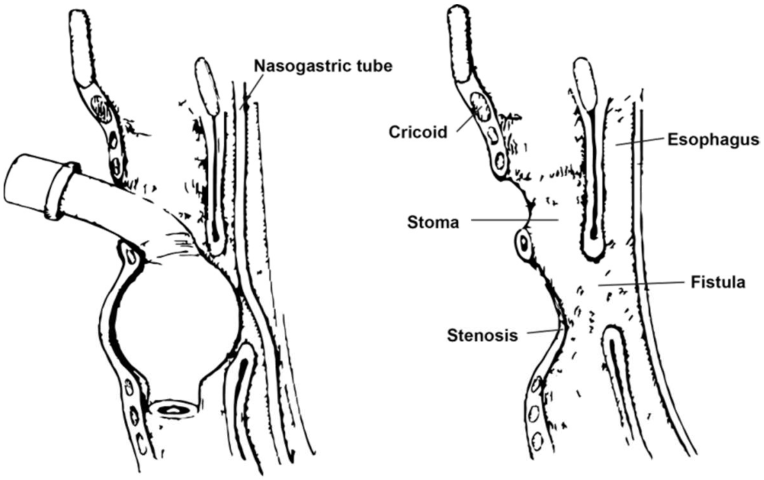
[2] Carol Davila University of Medicine and Pharmacy, Bucharest
[3] University Emergency Hospital, Bucharest

tracheoesophageal fistulas were more common when the high cuff pressure tubes were used. Once with the use of tubes with high volume and low pressure cuff, the incidence of fistulas has dramatically dropped down. In the international literature the occurrence of these fistulae has a relatively low frequency, of approximately 1% [4, 5, 6].

The widely accepted indication is that the cuff pressure tube should not exceed 25 cm H_2O and the volume should ideally be of 6-8 ml air. More than 10 ml of air should raise the question about tracheal injury. There are data from multi-center studies which have shown dangerously high cuff pressure after patient mobilization. These recommendations are given after multiple multi-center, international researches, but the low pressure cuff has the same danger like the high-pressure ones. If the trachea is not fully secured, then the patient is prone to tracheobronchial aspiration, despite the good and high efficient nursing [7, 8].



© 2016

The tracheostomy does not reduce the risk of tracheoesophageal fistula, the cuff of the cannula can injure the trachea in the same way. If the cannula's material is too rigid, the direct injury of tracheal wall may become possible through angulation [2].

The other factors involved in the occurrence of tracheoesophageal fistula are the presence of rigid nasogastric or orogastric tube, anemia, malnutrition, hypoxemia, anxiety, changing positions in bed, steroid treatment, advanced age, low perfusion from severe shocks [9, 10].

Tracheoesophageal fistula are located usually at the superior half of trachea, and in case of tracheostomy, 1-2 cm below the stoma [10].

The diagnosis of tracheoesophageal fistula is difficult. Suspicion of fistula is based on clinical signs: loss of air from breathing circuit, air on gastric tube, recurrent pneumonia, etc. We can do clinical test by administering blue methylene on the tube, but the diagnostic choice remains the bronchoscopy, images of computed tomography and upper gastrointestinal endoscopy [8, 11].

Treatment is usually surgical; less invasive procedures can be performed particularly for smaller defects, consisting in placing endoscopic stents [12].

PATIENTS AND METHODS

We have started a large prospective multicenter study in two intensive care units, the Central Military Hospital and University Emergency Hospital, Bucharest, Romania. The study started in April 2016 and will finish in the end of 2020.

All patients admitted to the intensive care unit which required orotracheal intubation more than 7 days, with or without mechanical ventilation, will be enrolled. Each observation paper will be attached in a special sheet and will include all the monitored parameters.

The parameters which will be monitored: counting days of orotracheal intubation, the pressure in the tube cuff, presence or absence of gastric tube, nutritional status of the patient, and hemoglobin during hospitalization, necessary of inotropic substances, presence or not of steroid treatment. Bronchoscopy will be performed regularly for early identification of changes of tracheal wall.

RESULTS

The occurrence of this complication in the intensive care unit of Military Central Hospital Bucharest during last five years was zero among the admitted patients (about 1500/year).

From 2,800 patients which were intubated, 1,100 needed tracheoesophageal intubation or tracheostomy more than 48 h. It is obvious that incidence of tracheoesophageal fistulas is inferior compared to actual literature information. So, we are looking forward the results of this study, in this moment the data we have aren't enough for a conclusion.

DISCUSSION

Our study aim is to highlight exactly the incidence of tracheoesophageal fistulas among endotracheal intubated patients in the ICU and their determinant factors.

Early identification of these complications with direct impact on morbidity and mortality of patients is extremely important. Secondary occurrence of pulmonary fistula and subsequent contamination of the lung may results in severe suppurative complication. Prompt treatment, either conservative or surgical, should be immediately applied.

In conclusion, the occurrence of tracheoesophageal fistulas can be lowered by aggressive nursing measures and eliminating/correcting determinants, including days of orotracheal intubation.

CLINICAL PRACTICE

Ankylosing spondylitis and cardiovascular risk – Case report

Daniela Anghel[1], Lucian M. Ciobîcă[1], Silviu M. Stanciu[1], Ciprian V. Jurcuţ[1], Gabriel D. Stoicescu[1], Ioana A. Răduţă[1], Ancuţa Coca[1]

Abstract: *Introduction: Ankylosing spondylitis (AS) is a chronic progressive inflammatory disease of the axial skeleton and peripheral joints associated with HLA B27 antigen and with the predominance of the male gender (with an average between 20 and 30 years old).*

Case presentation

A 48 years old male patient was admitted to our clinic, having a long history regarding this disease since he was 16.

This patient has switched 3 therapies with anti TNF alpha agents until now, and we hope to obtain a good response for a long time.

During the treatment with Etanercept he presented an acute anterior uveitis which had a good response to therapy.

Conclusion: The ankylosing spondylitis management is complicated when we have the possibility to choose only three anti TNF alpha agents. If a patient does not respond to the first or second agent we are constrained to follow the last one. Therefore the principal problem regarding this special case is that the patient is non responder at the last agent. So the question that arises is witch will be the next therapy for this patient?

INTRODUCTION

Ankylosing spondylitis (AS) is a chronic progressive inflammatory disease of the axial skeleton and peripheral joints – asymmetric.

Its major characteristic is the early damage of the sacroiliac joint, ascending to ankylosis. The incidence is increased for males between 20 and 30 years old, thus most of the patients are associating a HLA B27 antigen. The existence of cardiovascular risk due to inflammatory rheumatic diseases is known for decades but the real significance and therapy designed to control this risk has been recently evaluated.

Systemic inflammation because of inflammatory rheumatic diseases accelerates atherosclerosis and destabilizes plaque of atheroma, contributing to an increased frequency of fatal cardiovascular events such as myocardial heart attacks and strokes. The ankylosing spondylitis cardiovascular events include: aortic insufficiency, heart muscle damage (dilatation/hypertrophy), nerve impulse conduction disorders, pericarditis, and accelerated atherosclerosis.

Anti TNF-alpha therapy leads to a decrease of the disease activity score (BASDAI) and also the nonspecific inflammatory syndrome.

The anti TNF approved drugs which are currently in clinical practice are:

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest

1. Infliximab (*Remicade®*) – chimeric monoclonal antibody anti-TNF alpha;
2. Adalimumab (*Humira®*) – fully human monoclonal antibody anti –TNF alpha;
3. Etanercept (*Enbrel®*) – a fusion protein between the type 2 p75 receptor of TNF and an IgG1 Fc fragment.

CASE PRESENTATION

We present the case of a man, A.I., 48 years old, from urban medium, nonsmoker, having an insignificant family history, diagnosed since 1982 when he was 16 years old with juvenile arthritis.

He came for the last hospitalization, for clinical and biological reassessment, with ankles light arthralgias.

From his medical history we know that the disease has started when he was 16 years, with ankles and knees arthritics, at radiocarpal joints, at bilateral elbows, acute back pain and fever. The patient was diagnosed with juvenile arthritis and treated with Sulphasalazine 6 grams and nonsteroidal anti-inflammatory drugs. Under this treatment he had a slightly favorable evolution with partial improvement of symptoms. After 2 years of treatment disease flares have appeared, therefore the dose of Sulphasalazine at 8 grams/day was increased and a quantity of Methotrexate 7.5 mg/week was also added. After 1 year his clinical and biological evolution became favorable and the dose of Sulphasalazine was reduced to 4 grams/day, keeping Methotrexate and nonsteroidal anti-inflammatory drugs at the same dose. In 1998 he was diagnosed with ankylosing spondylitis according to the New York criteria and the association of HLA-B27 antigen. The patient gave up Methotrexate, the swelling and pain in large joints persisted so we increased the Sulphasalazine dose to 8 grams/day. The patient has annually done physio-kinesiotherapy. In 2009 it was decided to initiate biological therapy criteria (low back pain and morning stiffness, bilateral sacroiliitis grade 4, BASDAI 8.6) according to Guidelines for the treatment of ankylosing spondylitis.

In March 2009, the Infliximab (*Remicade®* 100 mg / fl) 5 mg/kg treatment was initiated. After a loading with Infliximab at 0, 6, 12 weeks, the patient had a clinically and biologically favorable development for 18 months.

Figure 1: Indications of biological therapies in ankylosing spondylitis by therapeutics protocols

Ankylosing spondylitis certain diagnostic according to the criteria of New York 1984:
• Low back pain and morning stiffness more than 3 months, being improved with effort and does not disappear at rest • Movement limitation of lumbar spine in sagital and frontal planes • Limitation of chest expansion • Unilateral or bilateral sacroiliitis grade 3-4 grade 2-4 (imaging criteria). • Diagnosis involves the imaging criteria presence (radiology, MRI) associated to at least one clinical criteria.
Active and severe disease
• BASDAI ≥ 6 for at least 4 weeks • Erythrocyte sedimentation rate > 28 mm/h • C reactive protein > 20 mg/L and 3 x VN (quantitated)
The failure of traditional therapies
•At least 2 nonsteroidal anti-inflammatory drugs continuously administrated for at least 3 months, at maximum recommended doses or tolerated for patients with axial forms • Patients with severe axial do not need a remitting (Sulphasalazine) before the biological therapy • Nonsteroidal anti-inflammatory drugs and Sulphasalazine in peripheral forms, at least 4 months of treatment at the maximum tolerated dose (3 g/d) • Ineffective response to at least one local administration of a corticosteroid injection in peripheral arthritis and/or active enthesopathies, if indicated.
The presence of hip joint damage and extra-articular manifestations are additional factors allowing anti-TNF therapy administration at a lower score of disease activity, with BASDAI ≥4

At the end of the year he suffered an acute infero-lateral myocardial infarction. The patient was hospitalized in the cardiology department, a coronary angiography was performed which revealed a 80-90% anterior descending artery stenosis, to the distal 50-60% left coronary artery stenosis, 80% stenosis in the origin of the AC, 90% oblique median artery stenosis.

The biological therapy was stopped and a surgical intervention was performed with a triple coronary artery bypass graft with autologous saphenous vein.

A carotid Doppler ultrasound was performed showing that carotid vascular system was without hemodynamically significant stenosis. Cardiac ultrasound revealed (left ventricular hypertrophy with anterolateral myocardial contractility low post, left ventricular ejection fraction 55%). Three months postoperatively the biological therapy with *Remicade®* was restarted but the second adverse reactions has occurred (generalized rash, severe hypotension). The patient received Sulphasalazine 6 grams/day, painkiller, intermittent nonsteroidal anti-inflammatory drugs and cardiological medication. Biological evaluation showed a mixed dyslipidemia, associating a grade 1 obesity.

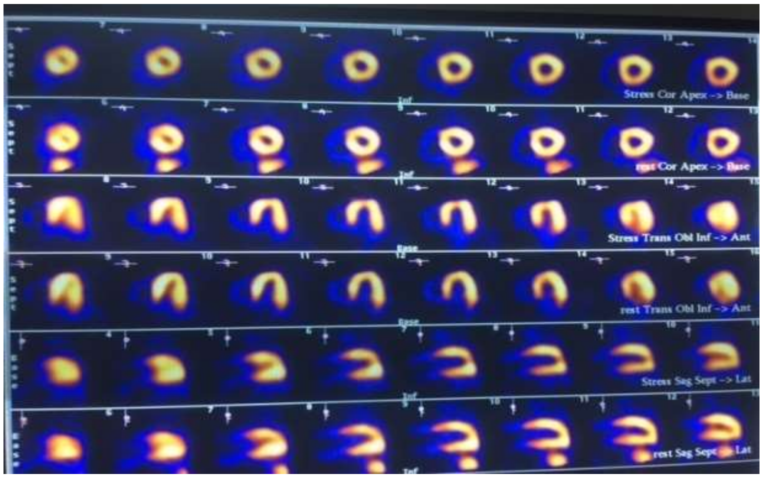
Rheumatic symptoms were significantly exacerbated (peripheral arthritis and low back pain, intense predominantly nocturnal), thus it was decided to initiate therapy with another anti-TNF alpha (*switch*) respectively Adalimumab (*Humira*®). In February 2011 a first dose of Adalimumab – *Humira*® 40 mg/2 weeks sc was administrated.

After 6 months of biological treatment with Humira, the following peripheral arthritis, acute lombalgy and inflammatory syndrome have persisted, BASDAI score was 8.1 and anginous pain occurs during small efforts. The angiography was repeated after which angioplasty was performed. Cardiac ultrasound is performed together with control cardiac stress tests, highlighting a grade 2 mitral regurgitation, posterior mitral ring atheromatosis, hypokinesia in the left ventricle lower part. Our patient had high blood pressure values being diagnosed with a 2 grade essential hypertension, thus instituting a antihypertensive therapy treatment. Therapeutics commission (rheumatologist – cardiologist) has decided to interrupt the biological therapy, considering the patient as being non responder according to the guide treatment ankylosing spondylitis criteria. The patient has continued the background therapy with Sulphasalazine 8 grams/day, pain relievers and cardiological medication.

Persistent inflammatory syndrome associated with peripheral arthritis (*de novo*, costo-vertebral arthritis and intense bilateral talalgia), BASDAI score was 9.1, has imposed a board therapeutic meeting whose opinion was to switch on the last anti TNF alpha, which remained the only therapeutic option, Etanercept (*Enbrel®* 50 mg/week).

Before the Enbrel therapy initiation a whole-body bone scintigraphy was performed (osteogenic lumbar spine and right acetabulum reactions), CT abdominal-pelvic (grade I hydronephrosis left kidney, left kidney chronic pyelonephritis) and TB QuantiFERON test (negative) to exclude a subclinical tuberculosis infection.

Figure 2: Myocardial Perfusion Scintigraphy



After 3 months the patient has presented a favorable evolution with a significant remission of the biological inflammatory syndrome, the peripheral joint tumefactions, persistence of a moderate intensity arthralgia and improvement of overall mobility. The patient was cardiologically reassessed, renal without the evidence of evolutionary elements. An angiocoronarography control was conducted (with 50% restenosis of the anterior descending artery stent), together with a myocardial treacherous tomoscintigraphy ECG synchronized (infero-septal dyskinesia level and decreased left ventricular ejection fraction regional effort – stress left ventricular ejection fraction 49%, resting left ventricular ejection fraction 60 %).

In 2014 the patient experienced an episode of acute anterior uveitis treated with corticosteroids and local mydriatic.

At the last hospitalization in February 2016 the clinical and biological evolution of the patient was favorable, the BASDAI score was 1.6. The treatment include *Enbrel®* the 50 mg/week, Sulphasalazine 1.5 grams/day, and nonsteroidal anti-inflammatory drugs intermittently. The patient is monitored at every 3 months by the rheumatologist and cardiologist and monthly by the family physician evidence the early possible complications.

Particularities of the case

1. Patient with juvenile arthritis, with ankylosing spondylitis evolution and complexes cardiovascular complications;

2. Lack of response to anti-TNF alpha 2 (*Remicade®*- side effects and *Humira®* - non responder);

3. Favorable answer and sustained to the 3rd anti TNF alpha (*Enbrel®*) after 3 years of treatment.

CONCLUSIONS

The introduction of TNF-alpha anti agents in treatment guidelines of ankylosing spondylitis, has revolutionized the therapy of patients with this disease, efficiency confirmed by numerous international clinical trials.

Anti TNF-alpha agents by reducing systemic inflammation creates a real cardiovascular protection for patients with ankylosing spondylitis, aspect highlighted for the case of our patient who has presented progressive cardiovascular events.

The complexity of the presented case is revealed by the associated comorbidities (cardiovascular, ocular, osteoarticular), which responded favorably after two switches of anti TNF-alpha concluding that switch between anti TNF alpha may be an effective therapeutic option in controlling the underlying disease and its complications.

Debut at the young age and association with HLA B 27 antigen are unfavorable prognostic factors for cardiovascular complications.

Interdisciplinary collaboration (rheumatologist, ophthalmologist, and cardiologist) is important for the management of patients with ankylosing spondylitis.

The evolution of this ankylosing spondylitis case is to be followed and the initiation in case of non-responder to *Enbrel®*, with a anti IL type 17 therapy, with sustained international studies having very good results in controlling this disease.

Behçet disease – Case presentation

Lucian M. Ciobîcă[1], Sârbu Iolanda[1], Silviu M. Stanciu[1], Ancuţa Coca[1]

Abstract: *Behcet's disease is a rare and poorly understood condition with multiple systemic manifestations. The disease causes inflammation in blood vessels throughout the body which leads to numerous symptoms that may appear and disappear unpredictable.*

Case presentation

A 33 year old woman was admitted (interned) to our clinic. Her family medical history reveals – multiple strokes (father) and autoimmune thyroiditis (sister).

The onset of her symptomatology was in 2013 and it consisted of fever (39-40 Celsius degrees) sicca syndrome and persistent headaches, recurrent oral and genital ulcerations.

An important event is essential to be mentioned -the patients has suffered an episode of upper gastrointestinal bleeding (hemoglobin has dropped to 2.5g/dl which has led to cardiac arrest-resuscitated).

The lab tests showed: C3 hypocomplementemia, Anti-centromere antibodies (-), anti-b2gp1 antibody (+), lupus anticoagulant (+), U1RNP(-).

We started to administrate cyclophosphamide to the patient, thus his condition has improved after the 2nd dose.

At the 12-month evaluation we were able to see a significant clinical and biological improvement.

Conclusions

In order to be able to talk about "evidence based medicine" for the management of Bechet's disease, a large number of clinical trials is required to provide to the attending physicians the necessary data for diagnosis and treatment.

INTRODUCTION

Behcet disease is a rare condition with a sinusoidal evolution which can affect almost all the organs and human systems, determining multiform symptoms with a variable severity. The medical practitioner has at his disposition a diversity of therapeutic options (from symptomatic therapy to a major systemic immunosuppression); at this moment we can't discuss about fundamental therapeutics protocols and unanimously recognized.

Behcet disease is an inflammatory systemic condition with an uncertain etiology. In the disease pathogenesis both environmental and genetic factors are involved like for the majority autoimmune diseases. This disease has been worldwide described but the maximum prevalence is registered in Middle East, adjacent zones of Mediterranean Sea and Asia

Considering the potential muco-cutaneous, articular, ophthalmic, neurologically, etc. damages, the interdisciplinary collaboration becomes more important. Due to the lack of specific guidelines for the diagnosis and treatment, the therapeutic approach of

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest

individuals' cases still remains dependent on the doctor treating experience or on the clinics where these complex cases are monitored.

CASE PRESENTATION

A 33 year old woman was admitted to our clinic presenting severe muscle weakness and joint pain.

Her medical history has revealed that in the last years the patient was admitted several times in the Infectious Diseases department with persistent fever and severe headaches.

Her family medical history has revealed – multiple strokes (father) and autoimmune thyroiditis (sister).

The onset of her symptomatology was in 2013 and it consisted of fever (39-40 degrees Celsius) sicca syndrome and persistent headaches. As the disease was progressing, our patient presented oral ulcerations, odynophagia, muscle weakness and blindness of the left eye.

The onset of the decreased visual acuity started with the right eye. An ophthalmologic examination has revealed uveitis and chorioretinitis.

Considering an inflammatory demyelinating disease (multiple sclerosis), the neurological exam suggested a cranial magnetic resonance imaging (which has revealed optic nerve edema) and anti-aquaporin 4 antibodies screening (which was negative). The patient treatment has started on Corticosteroids (methylprednisolone in pulse therapy) resulting a slight improvement of visual acuity, persistent joint pains, xerophtalmia.

An important event is essential to be mentioned -the patients has suffered an episode of upper gastrointestinal bleeding (hemoglobin drops to 2.5 g/dl which leads to cardiac arrest – resuscitated).

When the patient was admitted to our clinic the symptoms become more aggressive; the patient present extreme fatigue (with orthostatic intolerance), recurrent oral and genital ulcerations, odynophagia (due to the pain caused by oral and esophageal ulcerations she was not able to solid food or liquids) and blindness of the left eye.

Figure1: Atrophy of retinal layer

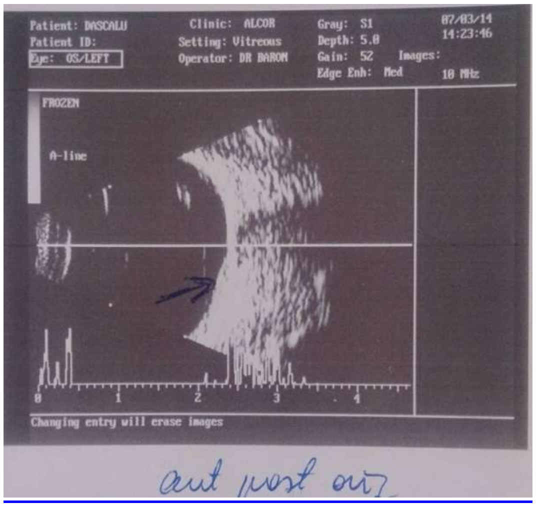

Figure 2: FOS – thicknesses of retinal layer

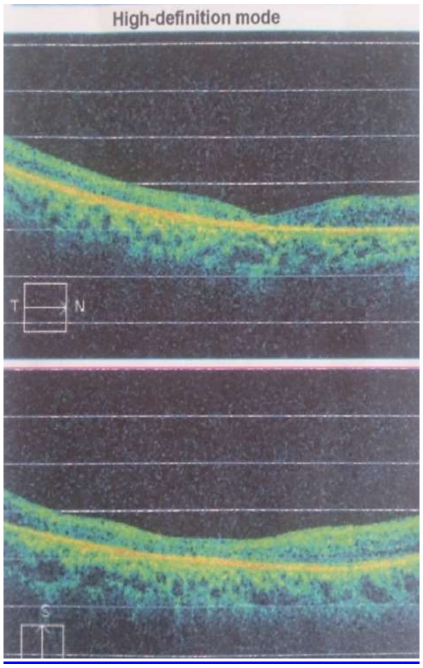

Despite the muscle weakness and severe fatigue that the patient suffered from throughout this whole period, muscle enzymes was never elevated.

Nevertheless we continued our investigations with an electromyogram. The EMG showed acute polymyositis aspect and sensory polyneuropathy lesion.

Then neurological exam showed spastic paraplegia, left brachial plegia and visual acuity loss. The brain MRI revealed a lacunar ischemic stroke in the vertebrobasilar territory.

The ophthalmological exam showed optic nerve atrophy.

We were facing with a patient, having a chronic, inflammatory multisystem condition of unknown etiology. The blood tests revealed nothing but a persistent inflammatory syndrome (ESR = 80-100 mm/h); the immunology tests didn't provide enough information either (C3 hypocomplementemia, Anti-centromere antibodies (-), anti-B2GP1 antibody (+) lupus anticoagulant (+), U1RNP (-), anti-aquaporin 4 antibodies (-) HLA B51 (-), Leiden V factor (+), ANA (+).

However we were in possession of his clinical examination highlights: chronic fatigue, recurrent mucosal ulceration, neurological symptoms, bilateral posterior uveitis, inflammatory arthritis various symptoms that we were able to identify as features of Behcet's disease.

By the time an accurate diagnostic could be established, the patient had already suffered some severe life threatening complications: upper GI bleeding with severe anemia that led to cardiac arrest, severe sepsis caused by infected decubitus injuries and medullar aplasia caused by high dose of immunosuppressive medication.

Behcet disease – generally accepted therapeutic objectives:

1. It's essential having a clear diagnostic and well founded as well as a clear setting of a lesional exact balance, with the progressive potential appreciation of the identified lesions;

2. The remission induction and maintenance;

3. The prevention of irreversible organs lesions (for example the ophthalmological one), which tends to appear early, especially in some problematic groups like young men;

4. The articular and muco-cutaneous exacerbations prevention can significantly improve the quality of life;

5. The multisystem involvement imposes for most cases interdisciplinary implication.

We want to underline the importance of having an accurate and precise diagnostic before starting a treatment, but in this particular case, a rapidly evolving disease worsened by the upper mentioned events, we decide that it was extremely necessary for the patient to start a remissive treatment. We initiated a moderate dose of cyclophosphamide (800 mg – 15 mg/kg bolus intravenous) and a low dose of oral corticosteroid (methylprednisolone 8 mg).

A significant improvement was observed after the second course of cyclophosphamide. The patient has regained the strength and muscular tonus, neurological symptoms has disappeared and she did no longer mucosal ulcerations.

Although the inflammatory ocular symptoms were suppressed, the significant loss of visual acuity persisted (it was caused by initial optical neuritis).

At the 12-month evaluation we were able to see a significant clinical and biological improvement. The patient is now able to do her daily activities therefore her lifestyle has improved.

The brain MRI shows normal brain parenchyma, normal vascular structures and normal blood flow.

Ophthalmological exam: minor restant vitrean abnormalities.

CONCLUSIONS

In the past decade we have witnessed a significant improvement in the therapeutic approach of Behcet's disease by optimal use of the old available drugs and also by the development and clinical use of new therapeutic solutions.

Behcet's disease still remains a multidisciplinary challenge for attending physicians.

Available data in the medical literature consists mainly in clinical cases and series of clinical cases with a limited statistic value.

In order to be able to talk about "evidence based medicine" for the management of Bechet's disease, a large number of clinical trials is required to provide for the attending physicians the necessary data for diagnosis and treatment algorithms.

VARIA

In memoriam – Cristian Babalâc (1954-2006)

Dan Mischianu

I am absolutely convinced that you have never wondered what the etiology of the *ferpar* word is.

The Romanian *ferpar* has its origin linked to the French "fair-part", which, according to the dictionary means a letter "announcing birth, engagement, marriage or, most often someone's death". The above lines are not intended to be a late *ferpar.*

These lines are supposed to bring back the memory of an absolutely exceptional man, a thorough man and a fighter, a true military doctor - Col. Dr. Cristian Babalâc (1954-2006), my University colleague. I also hope that these lines will make you realize that time passes quickly destroying everything on its way.

And time, a decent gentleman for some, covering us with a veil of forgetfulness, time "has a bad habit of being irreversible", as we learned from Octavian Paler.

Our desire is to present the portrait of the man, the military doctor, the professional Cristian Babalâc, because Dr. Cristian Babalâc was – and "to be" in the past tense sounds so sad! – a devoted man and practitioner that always proved an absolute professional availability.

My group colleague and my friend, Dr. Cristian Babalâc was born in Bucharest, on 13 January 1954 on Teodosie Rudeanu street, near North Railway Station, a few hundred meters from the Institute of Military Medicine, the place or "origin" of our emergence, the ones from yesterday, today and future serving Romanian military medicine.

Graduated from High School "Ion Neculce" Bucharest (1973), Faculty of Medicine Bucharest (1979), Doctor of Medicine with the thesis "The value of laser in the surgical treatment of soft part tumors" (1997), specialist doctor in Orthopedics and Traumatology (1989), Senior researcher (1990), consultant in Orthopedics and Traumatology (1995).

He participated as a member or responsible at research contracts, guided numerous diplomas and internships, conducted/aided the full range of orthopedics – traumatology procedures, 15 patents and 7 innovation patents for different medical devices: gurney for the transport of traumatized, forearm electronic prosthesis controlled by sensors, bioelectronic prosthesis for superior limb, immobilizer and transportation device for polytrauma patients, external bipolar monoplane fixator, semicircular external fixator, circular external fixator, universal external fixator, grapples for osteotomy. He introduced "CO_2 surgical laser treatment in musculoskeletal limb tumors" for the first time in the country.

Published the treatise: "Laser in the treatment of musculoskeletal diseases" (co-author) Military Publishing House Bucharest (1999), "Course of emergency and disaster medicine" (co-author) MTM Publishing, Consult Publishing (2003), 147 (20 as first author) communicated papers at congresses, conferences, symposiums in the country and abroad, 28 articles (4 as first author) published in journals: "Journal of Military Medicine", "Journal of Orthopedics and Traumatology", "News Update", "Balkan Military Medical Journal", a member of SOROT – Romanian Society of Osteoporosis Treatment, Romanian Society of Laser in Medicine and Biology, Romanian Association of Military Physicians and Pharmacists.

I knew him as a student and we operated together as specialist surgeons. Dr. Cristian Babalâc was a hard worker by definition, an absolute perfectionist, continually dissatisfied with his achievements – although he managed to accomplish everything he undertook, a deep thinker, a cerebral man, a genuine family man.

He was particularly pleased with the silence at home, the achievements of his wife, the distinguished Head of Hospital Pharmacy of "Prof. Theodor Burghele" Hospital – Ms. Pharmacist Gabriela Babalâc, and the professional accomplishments of their son – Cătălin Babalâc.

Col. Dr. Cristian Babalâc was a "serious man", a professional of orthopedics and traumatology of the Central Military Hospital. Nevertheless, medicine is very often defeated by disease severity.

I confess that I had a sense of absolute helplessness when I was near the bedside of Dr. Cristian Babalâc!

Lack of health, the implacable decline, and the mortal character of all beings – but most of all those close to our soul – are almost unapproachable subjects. As I was writing these lines I was overwhelmed by bleak thoughts.

My intention was only one, to restore the memory of those who knew and valued him, a decade after his passing, the luminous figure of Dr. Cristian Babalâc, although "slightly frown as a result of the multitude of his thoughts".

Leaving us ten years ago after unimaginable suffering, I think Dr. Cristian Babalâc kept one hope in his noble and good soul: maybe better is yet to come!

May God bless his soul!

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine*. Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/ mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must

comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

EDITORIAL

About health, with hope

Dan Mischianu

Gral (R) Prof DAN MISCHIANU
Chief of Urology Clinic, Carol Davila Central Emergency Military Hospital
Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Health is an extremely complicated subject, but to talk about health is like howling in a cave: anyone can hear, no one understands! ...maybe only the echo?!

The World Health Organization (WHO) proposed in 1948 when it was established, the following definition: "Health is a fully favorable physically, mentally and socially status, not merely the absence of disease or infirmity." Then came an addition: 'ability to lead a productive life, socially and economically. "

I recently finished reading a bestseller also promised to the Romanian reader by Polirom publisher "Sapiens A Brief History Of Humankind" Yuval Noah Harari, Vintage Books, London, 2014. A strange creature this "homo sapiens" is, strange since all his derivatives propose other approaches and other perceptions on the concept or "health"! To primordial "sapiens" health had other connotations...

Perhaps they were cleverer, crueler, and that is why they prevailed and multiplied logarithmically. Then the diseases appeared: congenital, posttraumatic, neoplastic, infectious and so on...

Returning to our nation, Romanians produced with unmistakable grace many sayings, in which they truly believe: "Health is better than all!", "Health is the best wealth!"

Or, pessimistically "Until you're sick, you cannot be healthy!"

The traditional stories regarding health record something else: "Health, contentment and trust are your most valuable possessions and freedom is the greatest joy of yours."

I am absolutely convinced that we all want to reach or to "apply" (Anglo-Saxon term) to an entity which we believe is intangible: "Health comes first!"

Unfortunately, after we solve almost all our goals and desires, we find that health left at the end, it is "unsolvable"!...

Romanians deep and law abiding Christians, ancestral pessimistic have another saying "Cherish health when you lose it!"

Even I do not understand this allegory, why?

Because I work in a field that many pretend to understand, but few have deciphered the "anatomy and physiology" of its development, an area where financiers who led it wanting to make a profit, now keep their mouths shut nor can i forget that there were great men, deciding the destiny of many nations, who had a absolutely unfortunate history of "health": Emperor Napoleon III died in urosepsis under the supervision of the most famous urologist of its time, Emperor Wilhelm II, the first grandson of Queen Victoria of the United Kingdom, born with left brachial plexus palsy after a labor dystocia (1859), "irritable, angry, violent and passionate" started The First World War and Generalissim – Iosif Vissarionovich Stalin's apparently had the same malady that which made him as reckless and cruel.

They followed, and still follow many others, the bad, and the complexed!

It is these thoughts that make me not to forget Miron Costin's assertion: "There are times under the man, but the poor man under these times." ("Chronicle of Moldavia after Aron Voda").

For this editorial, unfortunately slightly skeptical about the future, it will appear in the new year 2017 I ask the reader of these lines to believe and hope that Romania will benefit from a new configuration of a credible, effective and with a tendency towards the many health system.

I further wish you a happy New Year full of accomplishments, or, as people say in our country, “A Happy New Year!"

REVIEW ARTICLE

Article received on March 7, 2016 and accepted for publishing on August 25, 2016.

Capabilities for identification and confirmation of bacterial biological agents

Diana M. Popescu[1], Marius Necșulescu[1], Lucia E. Ionescu[1], Simona N. Bicheru[1], Gabriela V. Dumitrescu[1], Viorel Ordeanu[1]

Abstract: *Military Medical Service is able for detection, identification and confirmation of biological agents; it is part of medical protection against CBRN weapons. We are specialized capabilities for in vitro tests, under construction, the maximum containment laboratory designed for work with Risk Group Microorganisms. An efficient primary containment system must be in place, consisting of one or a combination of the following: Class III safety cabinet laboratory, passage of two doors, suit laboratory, controlled access, controlled air system. Negative pressure in the facility, supply and exhaust air must be HEPA-filtered, decontamination of effluents, sterilization of waste and materials, airlock entry ports for specimens, materials and animals must be provided etc. Complementary is an Animal facility for in vivo tests. This is suitable for work with animals that are deliberately inoculated with microorganisms in Risk Group.*

Keywords: *biological security, military capability, biological attack, biological agents, CIMIC, medical protection*

CAPABILITIES FOR IDENTIFICATION AND CONFIRMATION OF BIOLOGICAL AGENTS

Military Medical Service is abilities for the detection, identification and confirmation of biological agents. It is part of the medical protection against CBRN weapons, with mobile and stationary capabilities. MMRC participate, specifically the medical protection against biological weapons and bioterrorism with a series of microstructures: Biological mobile intervention team with mobile platform; Biological analytical laboratory CBRN defense, integrated platform for scientific and medical-military research for biological agents, with: Laboratory of Microbiology high secure, Secured animal facility laboratory for confirmation of biological agents, laboratory of molecular biology and genetics, toxicology laboratory and Annex facility. [1, 2, 3, 4]

SPECIALIZED CAPABILITIES

Stationary

The maximum containment microbiological laboratory is designed for work with Risk Group Microorganisms, for in vitro diagnostic. Operational maximum containment laboratories should be under the control of national or other appropriate health authorities. [5,

---

[1] Military Medical Research Center, Bucharest

6]

Laboratory design and facilities:

- Primary containment. An efficient primary containment system must be in place, consisting of one or a combination of the following; Class III cabinet laboratory. Passage through a minimum of two doors prior to entering the rooms containing the Class III biological safety cabinet is required; [5, 7] Suit laboratory. A protective suit laboratory with self-contained breathing apparatus differs significantly in design and facility requirements from a Biosafety Level 4 laboratory with Class III biological safety cabinets. [5]

- Controlled access. The maximum containment laboratory must be located in a separate building or in a clearly delineated zone within a secure building. Entry and exit of personnel and supplies must be through an airlock or pass-through system. [5, 8, 9, 10, 11]

- Controlled air system. Negative pressure must be maintained in the facility. Both supply and exhaust air must be HEPA-filtered. There are significant differences in the ventilating systems of the Class III cabinet laboratory and suit laboratory. [5]

- Decontamination of effluents. All effluents from the suit area, decontamination must be decontaminated before final discharge. Heat treatment is the preferred method. Effluents may also require correction to a neutral pH prior to discharge. Water from the personnel shower and toilet may be discharged directly to the sanitary sewer without treatment. [5, 8, 9, 10]

- Sterilization of waste and materials. A double-door, pass-through autoclave must be available in the laboratory area. Other methods of decontamination must be available for equipment and items that cannot withstand steam sterilization. [5, 6]

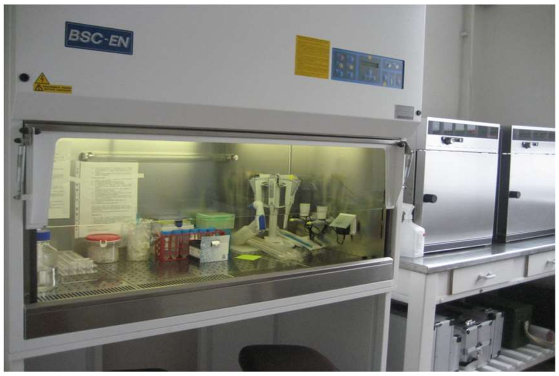
- Airlock entry ports for specimens, materials and animals must be provided. [5]

- Emergency power and dedicated power supply lines must be provided. [6]

- Containment drains must be installed. [5]

Because of the great complexity of the engineering, design and construction of Biosafety Level facilities, in cabinet or suit configuration, schematic representations of such facilities have not been included. [5] (Figure 1)

Figure 1: Microbiological laboratory for biological agents



Animal facility

This is suitable for work with animals that are deliberately inoculated with microorganisms in the Risk Group, for in vivo diagnostic. [12, 13, 14] The following safety precautions apply:

- All the requirements for animal facilities – Biosafety Level must be met. [12, 13, 14, 15]
- Biohazard warning signs (see Figure 1) should be posted on doors and other appropriate places. [12, 14]
- The facility must be designed for easy cleaning and housekeeping. [12, 14]
- Doors must open inwards and be self-closing. [12, 14]
- Heating, ventilation and lighting must be adequate. [12, 14]
- If mechanical ventilation is provided, the airflow must be inwards. Exhaust air is discharged to the outside and should not be recirculated to any part of the building. [12, 14]
- Access must be restricted to authorized persons. [12, 14]
- No animals should be admitted other than those for experimental use. [12, 14]
- There should be an arthropod and rodent control program. [12, 14]

- Windows, if present, must be secure, resistant to breakage and, if able to be opened, must be fitted with arthropod-proof screens. [12, 14]
- After use, work surfaces must be decontaminated with effective disinfectants. [12, 14]
- Biological safety cabinets (Class II) or isolator cages with dedicated air supplies and HEPA-filtered exhaust air must be provided for work that may involve the generation of aerosols [12, 13, 14, 15, 16]
- An autoclave must be available on site or in appropriate proximity to the animal facility. [12, 13, 14, 15, 16]
- Animal bedding materials must be removed in a manner that minimizes the generation of aerosols and dust. [12, 13, 14]
- All waste materials and bedding must be decontaminated before disposal. [12, 13, 14]
- Use of sharp instruments should be restricted whenever possible. Sharps should always be collected in puncture-proof/-resistant containers fitted with covers and treated as infectious. [12, 13, 14]
- Material for autoclaving or incineration must be transported safely, in closed containers. [12, 13, 14]
- Animal cages must be decontaminated after use. [12, 13, 14]
- Animal carcasses should be incinerated. [12, 13, 14]
- Protective clothing and equipment must be worn in the facility, and removed on leaving. [12, 13, 14]
- Hand-washing facilities must be provided. Staff must wash their hands before leaving the animal facility. [12, 13, 14]
- All injuries, however minor, must be treated appropriately, reported and recorded. [12, 13, 14]
- Eating, drinking, smoking and application of cosmetics must be forbidden in the facility. [12, 13, 14]
- All personnel must receive appropriate training. [12, 13, 14]

This facility is complementary to the microbiological laboratory (Figures 2, 3).

Figure 2: Animal facility for microbiological diagnosis

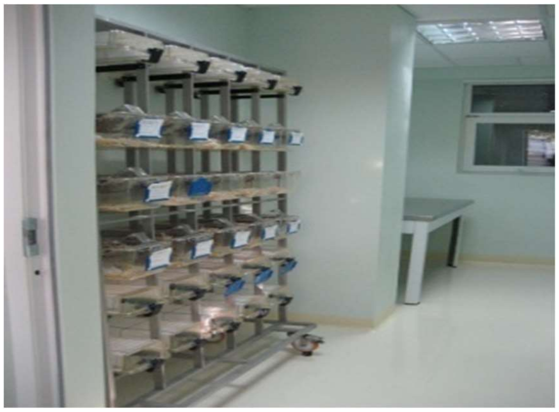


Figure 3: Secured animal facility laboratory

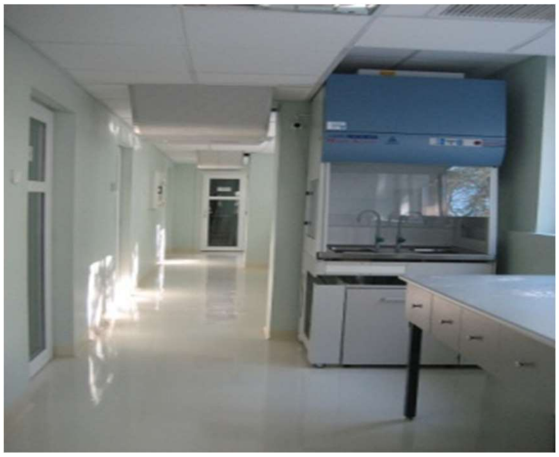


SPECIALIZED MOBILE CAPABILITIES FOR Bio-Det SYSTEM

Specialized Mobile capabilities for Bio det system:

- provides monitoring, sampling, detection and identification;
- detects long line releases and identifies up to 6000 species and sub-species (data base).
- up to 96 samples can run simultaneously, no time needed to re-deploy.
- deploy worldwide and conduct biological surveillance operations in order to provide identification of biological agent employment.
- provide information to other forces (rescue teams, medical, etc)

Bio-Det Systems

Configuration:

- Vehicle with 2 internal compartments, with power supply, specific furniture and safety cabinet class III.

For monitoring: Verotect – determines if a bio-mass is present within aerosol particles of a certain size range

For identification:

- MALDI TOF Microflex LT 20 with vehicle mount
- Water, soil and air sampling kits
- Sample preparation equipment (incubator, centrifuge, freezer, autoclave, handling tools, consumables and reagents)

Miscellaneous:

- Personal protection for the operators (suits, masks, oxygen tubes)
- Hardened laptop etc.

Mass Spectrometry

Those are complex instruments which record an ionic flow as a spectrum, in relation to both mass and the relative occurrence of the ions; Mass spectrometry is a confirmation analytical technique which allows identification of organic compounds, based on the mass/electrical charge ratio of the molecule fragments of the analyze.

The mass spectrometer consists of 4 elements: sample loading port, where a certain amount of sample is introduced at the required pressure in order to be exposed to the ion source and to be ionized at maximum efficiency. Ion source, where the neutral atoms and molecules are ionized and directed into the instrument as a monenergistic bundle.

Mass (energy) analyzer, which by electrical and/or magnetically deflections selects the ions according to the q/m values, their masses, concomitantly focusing them towards an outlet gap. Detector, comprising the system which transforms the ionic flow either into a photographic image or an electric current that can be recorded with an appropriate instrument.

MALDI TOF Microflex

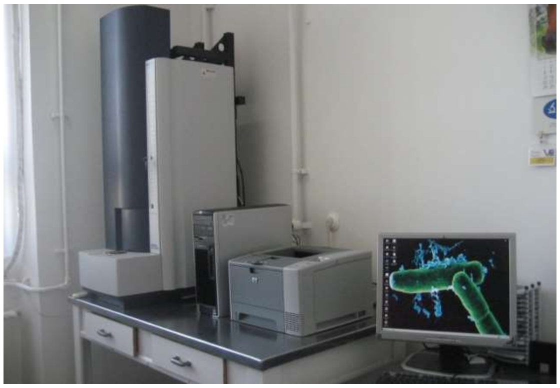
Microflex LT20 is a MALDI TOF system equipped with Bioprofiler software and it is used for the identification and taxonomic appointment of the biological agents from air, water, soil and other surfaces, after a previous specific processing of the collected samples. The main element is a MALDI TOF spectrometer, with a mass domain from 2,000 to 20,000 Da. The instrument is controlled by means of a computer with Windows operating system and specialized software (Bioprofiler). The data processing system controls all acquisition, saving and storage processes of the spectral information, allowing later processing of the information or access to the data base.

Microflex LT 20 Bruker system

It has the ability to identify the biological agents from various samples (liquid, solid, gaseous). Identification is performed by comparing the obtained spectrum to the existing data base of memorized biological agents.

The software indicates the matching of the spectrum under test with spectra from the database, according to the obtained scores. Scores are generated by evaluation and comparison between spectra and are not percents. If a biological agent is not included in the data library, the agent with the closest structure is exhibited, but the score indicates that the agent under test is not included in the data base of the instrument (Figure 4).

Figure 4: Mass spectrometer for microbiological diagnosis (The Microbiology Laboratory MMRC, I. Cantacuzino)



Operation steps Microflex

Preparation of samples for MALDI TOF analysis is done by extracting 16S ribosomal proteins that can be achieved by several techniques depending on the organism analyzed. [17]

The instrument can measure mass spectra from 2,000 up to 20,000 Da, i.e. a very wide range of organic molecules originating from any kind of biological agents (bacteria, spores, viruses, fungi, yeasts, toxins). The software and its data base are capable to identify biological agents of civil and medical-military interest.

The equipment is foreseen with a device for attachment to mobile laboratories, allowing its use in the field, either in campaigns or, in peace time, in case of biological events or crises.

The quality of the incorporated mass spectrometer as well as the structure of the soft that can be upgraded in time, strongly recommends the MALDI TOF – Bioprofiler MICROFLEX LT20 system for identifying biological agents, to be used for precise microbiologic diagnostic, species confirmation for the biological agent, medico-military research and medical defense against biological weapons or bioterrorist attacks.

Military Medical Service is able for detection, identification and confirmation of biological agents. It is part of medical protection against CBRN weapons, in civil-military cooperation (CIMIC). [17]

CONCLUSIONS

CCSMM has specific capabilities for scientific research for medical protection against CBRN WMD.

Anti-infective medical protection laboratory and Epidemiologic emergency laboratory have capability of performing detection, identification and confirmation of biological agents within the limits of available supplies.

The capacities and capabilities of health protection against biological weapons are interoperable with NATO.

Detection, identification and confirmation of the presence of bacterial biological agents are executed sequentially and modular, specialized capacities through cooperation, which must have the capability to perform these tasks.

The consequences of Chernobyl accident

Ion Chioșilă[1]

Abstract: *These days marks 30 years since the Chernobyl nuclear accident, followed by massive radioactive contamination of the environment and human in Belarus, Ukraine and Russia, and resulted in many deaths among people who intervened to decrease the effects of the nuclear disaster. The 26 April 1986 nuclear accident contaminated all European countries, but at a much lower level, without highlighted consequences on human health. In special laboratories, the main radionuclides (I-131, Cs-137, Cs-134 and Sr-90) were also analyzed in Romania from environmental samples, food, even human subjects. These radionuclides caused the population to receive a low dose of about 1 mSv in 1986 that is half of the dose of the natural background radiation (2.4 mSv per year). As in all European countries (excluding Ukraine, Belarus and Russia) this dose of about 1 mSv fell rapidly by 1990, reaching levels close to ones before the accident at the nuclear tests.*

Keywords: *nuclear accident, Chernobyl disaster, radionuclide, radioactive contamination, effective dose*

INTRODUCTION

2016 marks 30 years since the major accident in the history of nuclear power plants (active zone melting and thermal explosion) that took place on 26th April 1986 at 4th reactor of Chernobyl Nuclear Power Plant (Ukraine). Emissions of radio nuclides were particularly high and affected many countries in Europe, including our country. The 4 reactors in operation at the time run on natural uranium (U-238) with low-enriched U-235, a high producer of Pu-239 (strategic material for nuclear weapons).

Although this type of reactor was well known by the operating personnel, they conducted an experiment with the turbine running in the inertial mode and lowering reactor's power at 10%, but the return to full power (thousand MW) took only 2 seconds which led to a loss of control and the impossibility of an emergency shutdown of reactor no. 4. The rapid and uncontrolled increase in temperature of the reactor core produced two successive explosions seconds after each other that threw the 1000 tons concrete for protection, as well as large amounts of nuclear fuel with fission products and activation products, along with the burning graphite moderator [1].

Definitions of specific terms

1. Activity (radioactivity) of a radionuclide: the unit of work in the International System (S.I.), is one disintegration per second, or s-1, with the name Becquerel and symbol Bq. Curie - special name for the tolerated unit of the activity of a radionuclide, with the symbol Ci; is 3.7 x 1010 disintegrations per second

---

[1] Romanian Society for Radiological Protection, Bucharest

(approximate activity of radon – 222 in equilibrium with one gram of radium – 226) and respectively 3.7 x 1010 Bq.

2. Half-life – the time after which the number of nuclei of a radionuclide is reduced to half by radioactive decay with symbol T1/2, or Tf is used.

The biological half-life – the time required for a biological system to remove half of the nuclei (stable or radioactive) by metabolic processes with symbol Tb. The effective half-life – the time needed to halve the number of radioactive nuclei (activity) by decay and metabolic processes with Tef symbol.

3. Effective dose – weighted sum of equivalent doses from external and internal exposure, performed on all organs (tissues) of the body (the absorbed dose multiplied by the weighting factor of radiation and weighting factor of tissue or organ). In the S.I. unit is J/kg with the name Sievert and symbol Sv.

The effective dose limit for occupationally exposed workers – effective dose limit for people working in environmental radiation is 20 mSv per year. The effective dose limit for the population – effective dose limit for an individual in the population is 1 mSv per year.

CONTAMINATION OF THE ENVIRONMENT

Fission products (Cs-137, Sr-90, Sr-89, I-131, etc.) and activation products (Cs-134, Co-60, Fe-55, Fe-59, etc.) were released in atmosphere and transported by air currents throughout the northern hemisphere. The most affected (radioactive contamination) were Belarus, Ukraine and European Russia; less contaminated air currents reached many other countries in NW Europe (mainly Norway, Sweden, Finland), and to S and S-V Europe, inclusively to Romania.

Rainfall and dry deposition made possible contamination of the environment (soil, surface and biosphere).

Cs-137 was the easiest to detect (beta-emitting and gamma-emitting radiation) and has a great half-life period (Tf or 1/2) of approximately 30 years, for which most of the estimations of environmental and human contamination reported to this radionuclide.

Table 1: Surfaces contaminated with Cs-137 in some countries affected by the Chernobyl nuclear accident [2]

Country*)	**37-185 (kBq/m²)**	**185-1480 (kBq/m²)**	**over 1480 (kBq/m²)**
Russia	49800	7800	300
Belarus	29900	14400	2200
Ukraine	37200	4100	600
Sweden	12000	-	-
Finland	11500	-	-
Norway	5200	-	-
Austria	8600	-	-
Bulgaria	4800	-	-
Switzerland	1300	-	-
Greece	1200	-	-
Slovenia	300	-	-
Moldavia	60	-	-

*) In Romania, most of the surface was contaminated with Cs-137 with values below 2 kBq/m². There were large areas contaminated 2-10 kBq/ m² in Oltenia, Banat, N-E Moldova, central and northern Muntenia; here they were found locations with contamination exceeding 10 kBq/ m².

ASPECTS OF RADIATION PROTECTION IN ROMANIA

Monitoring environmental radioactivity and food radioactivity in Romania [1,3] was carried out by:

- 47 Environmental Radioactivity Monitoring Stations (belonging to the former National Council for Water, today 37 stations form the National Network of Environmental Radioactivity Monitoring and belongs to the Ministry of Environment)
- 22 Ionizing Radiation Hygiene Laboratories, of which 4 were from the Institute of Hygiene and Public Health in Bucharest, Iasi, Cluj and Timişoara (Ministry of Health)
- departamental laboratories (Institute of Atomic Physics – IFA Măgurele – Bucharest, Institute of Nuclear Energy Reactors – IRNE Pitești, Ministry of National Defense – MND, etc) (The Laboratory for radiochemistry of the Military Center for Medical Research also had tasks of human and environmental radioactivity monitoring in addition to the experimental research. There was also a laboratory to

measure the radioactive contamination of man (with whole body counter).

In the period immediately after the accident (the night of April 30, 1986 when contaminated air masses came first in the N-E) and in the years after the accident the following analyzes were performed:

- global beta measuring and gamma spectrometry of aerosol filters, total atmospheric deposition, surface and drinking water analysis, soil, wild vegetation and crops analysis, animal products and food menus from various canteens in Bucharest and in the country analysis
- direct measurement of radionuclides incorporated into man (I-131, Cs-137 and Cs-134) with MND and IFA whole body counter
- radiation dose exposure estimation for humans.

Among the measures taken for radiation protection of population in Romania, it is worth mentioning:
- consumer restrictions on certain foods (dairy products contaminated with I-131, Cs-137 and Cs-134) based on the values determined by measuring the radioactivity of food in the most contaminated counties
- forbidding sport events scheduled to take place outdoors on May 2
- administration of stable iodine for children, beginning with 3th May

Recommendations:
- extensive washing of vegetables before consumption
- reduced time spent in the open in the first week after the accident.

Negative aspects concerning the application of radiation protection measures:

- insufficient public information on the accident,
- KI administration started with a two days delay leading to reduced performance at about 50% and the administration was not performed at all children in areas contaminated with I-131.

ENVIRONMENTAL, FOOD AND HUMAN CONTAMINATION IN ROMANIA

After corroborating the results of radioactivity monitoring of the environmental factors, water and food, it was possible to create a map of radioactive fallout in our country in three stages: 1st to 2nd of May, 3rd - 4th of May and 5th to 6th of May respectively. So, the greatest contamination occurred due to the fallout of 3rd to 4th of May, which came from N-E and followed the Eastern and Southern Carpathians, with the southern area being the most contaminated (Figure 1) [4].

In atmospheric aerosols there were readings of a maximum of 103 Bq/m^3 for I-131, respectively 63 Bq/m^3 for Cs-137 at Toaca station in Ceahlău on 1st of May 1986; also readings of 17 Bq/m^3 I-131 and 14 Bq/m^3 for Cs-137 at Fundata station (Braşov county). These peaks declined rapidly in the second half of May and early June 1986, going as low as a 1000 times lower. Regarding the average concentration of Cs-137 in the aerosols, from about 106 Bq.s/m^3 in 1986 fell below 105 in 1987 and in 1991 it went back to the value from before the accident (about 200 Bq.s/m^3) [4,5].

Atmospheric radioactive depositions values were in 1986 over 3 orders of magnitude higher compared to before Chernobyl accident. As late as 1993 the average values of Cs-137 deposition reach 1 order of magnitude over that of 1985 because of wind carrying out the contaminated dust and returning in the form of radioactive fallout.

Average concentrations of Cs-137 in untilled soil samples were of 350 Bq/kg, with peaks in excess of 1000 Bq/kg in the northern county of Gorj. High levels of Cs-137 in untilled soil were recorded at Toaca-Ceahlău, Targu Mures, Gheorghieni and Parâng, with maximum levels of 2050 Bq/kg of dry soil.

In surface water, high values of Cs-137 were determined 2 or 3 days later than the atmospheric reading, measuring 50 Bq/m^3, with rapid drop below 10 Bq/m^3 in 1987 and 1988, returning to the values from 1985 as late as 1993.

The contamination of wild vegetation was carried out by fine radioactive particle deposition and measuring average values of Cs-137 as high as 1000 Bq/kg of dry vegetation, with values declining to before the accident in 1990. Contamination of crops by absorbing radionuclides in the soil was quite low, so radionuclide values decreased rapidly in the coming years [3].

The highest level of contamination with I-131 in food was found in ewe`s milk, with values of about 1300 Bq/L or higher, which led to temporary restriction in consumption imposed by the Ministry of Health, for dairy products. Cs-137 values in milk and dairy products were about 500 Bq/kg (Table 2). This radionuclide content in food has decreased since 1990, and since 2000 has reached the 1985 values.

Three stages of contamination in Romania: 🟥 1 – 2 🟨 3 – 4 🟦 5 – 6

Table 2: Content of Cs-137 (Bq/L or kg) in drinking water and foods [5, 6]

Food	**1986**	**1987**	**1988 - 1991**	2003
Water	-	0.05	0.002 – 0.009	0.002 – 0.009
Milk	10 - 200	27.92	1.02 – 5.13	0.01 – 0.137
Dairy products	10 - 500	61.98	5.07 – 16.61	-
Meet	50 - 300	47.50	1.31 – 39.25	0.014 – 10.28
Meet products	10 - 727	23.19	1.50 – 19.15	-
Grain products	50 - 100	42.16	1.01 – 12.15	0,251
Fruits and vegetables	7 - 411	46.43	1.89 – 23.39	0.037 – 0.265
Food menu/24 hours	-	23.69	1.50 – 4.49	-

If immediately after accident experts paid particular attention to radionuclides I-131 and Cs-137, easily determined by gamma spectrometry directly from samples, by the end of the year and in following years measurements were performed to determine the content of Sr-90 in water and food. Aerosols contamination levels with Sr-90 were less than 1/10 the levels of Cs-137 so the food contamination with Sr-90 was much lower, generally below 10 Bq/kg or L of product (Table 3).

Radionuclides Cs-137, Cs-134 and Sr-90, a little transferable from soil to plant, however they were detected many years after the accident; radioactive contents fell sharply in 1987 and then steadily, currently reaching in most foods well below 1 Bq/kg, hard to detect even with radiochemical analysis. There still are very low values for Cs-137 (units Bq/kg) in berries, mushrooms and wild venison.

Table 3: Content of Sr-90 (Bq/L or kg) in drinking water and foods [5, 6]

Food	1987	1988 - 1991	2003
Water	0.04	0.003 – 0.010	0.001 – 0.066
Milk	0.43	0.14 – 0.33	0.068 – 0.930
Dairy products	0.75	0.19 – 0.76	-
Meet	0.46	0.10 – 0.24	0.087 – 0.690
Meet products	0,62	0.09 – 0.20	-
Grain products	0.70	0.25 – 0.76	0.135 – 0.730
Fruits and vegetables	0.97	0.10 – 0.98	0.047 – 1.060
Food menu/24 hours	2.30	0.19 – 0.23	-

Assessment of human internal contamination with radionuclides I-131, Cs-137, Cs-134 and Sr-90 (Table 4) was performed both directly for the first three radionuclides (measuring radionuclides from humans) and by estimating the contamination based on the values of radioactive content determined in drinking water, food, and in real or hypothetical food menu (Table 2).

Table 4: Content of Cs-137, Cs-134 and Sr-90 in the human body (direct measurement/ estimation from ingestion of food) in Romania [6]

Radionuclide		1986	1987	1988	1989	1990	1991	1992	1993
Cs-137	measurement	1000 - 2000	2000 - 2500	800 - 1700	500 - 1100	300 - 500	< 300	< 300	< 300
	estimation	1538 - 20383	2335 - 12774	415 - 673	106 - 198	82 - 150	80 - 140	60 - 119	19 - 38
Cs-134	estimation	686 - 8703	729 - 4894	94 - 153	18 - 33	10 - 18	5 - 10	1 - 3	-
Sr-90	estimation	30 - 100	18 - 57	12 - 38	12 - 34	11 - 32	10 - 30	9 - 28	8 - 25

After about 80 days I-131 disappeared from humans and food through physical decay (if 10 Tf pass, it is considered that radionuclide decreases in values too difficult to determine; Tf for I-131 is 8.1 days). In terms of I-131 content found in thyroid, it presents very different values to a few thousand Bq only in May and June, depending on the level of contamination of the studied area and the food consumed. These rates were still much lower compared to human radioactivity/radiation dose received in the case of thyroid scintigraphy (tens - hundreds of kBq) [1,6].

For humans, Cs-137 + Cs-134, from about 2500 Bq in 1986 the values have gradually decreased to a point where after four years they went below 300 Bq. The loss of activity of the two radionuclides in humans was attributed to their reduction in food and to metabolic processes in the human body (Tb for the two radionuclides is 100-150 days) or by disintegration for Cs-134 (Tf = 2.05 years); so that after 1990 the Cs-137 values fell below the detection limit of the equipment used for the direct measurement. Sr-90 contamination for humans was much lower, estimated values below 100 Bq (radionuclide emits only beta radiation that can only be detected in small biological samples and the low contamination of foods did not allowed measuring this radionuclide in humans) [1,6].

ESTIMATION OF THE EXPOSURE DOSE FOR THE POPULATION OF ROMANIA

Immediately after the accident, Oncescu and Galeriu (IFA Bucharest – Măgurele) have calculated the exposure dose due to radioactive contamination of the population in our country which calculated to be about 1 mSv for the first year after the accident. Values are similar to those published by WHO (World's Health Organization) and IAEA (International Atomic Energy Agency) for other European countries (Finland: 0.44 mSv, Germany: 0.5 to 1.1 mSv, Italy: 0.61 mSv, Poland: 0.95 mSv, Switzerland: 1 3 mSv etc.) [1].

The subsequent calculation of the effective dose received by man from radionuclides determined in air, water and food for the most contaminated areas in Romania, except the contribution of I-131, resulted in average values close to 1 mSv in the first year after the accident, with a greater fall in 1988 (the greatest contribution to contamination was from Cs-137 and Cs-134 in food). Between 1990 and 2000 and now, the annual effective dose for humans fell below 50 µSv, values over 40 times lower than the dose received by humans from background radiation [4].

Figure 2: Exposure assessment of Romania's population – dose reconstruction by food based on Cs-137 concentration in atmospheric deposition [4, 5]. Minimum exposure dose of 0.2 mSv in Satu Mare County, maximum exposure dose of 2.1 mSv in Gorj County.

Doses of radiation exposure of the population in Romania after the nuclear accident vary by an order of magnitude between 0.2 and 2.1 mSv in the first year (Figure 2), based on contaminated air masses movement (Figure 1) as well as wet and dry deposition in our country. Thus, there were areas (counties) with quite small exposure doses, less than 0.5 mSv such as Satu Mare, Salaj, Maramures, Sibiu, Brasov, Harghita, while in other counties exposure doses were even over 1 mSv such as: Caras-Severin, Gorj, Mehedinți, Tulcea, Neamt, Vrancea, Teleorman.

The average dose received by most of the European countries of about 1 mSv is incomparably lower than that of more than 10 mSv received by population in heavily radioactive contaminated areas of Belarus, Ukraine and Russia. This dose of about 1 mSv in the first year after the accident is below the natural background exposure (irradiation) had a low radiological significance on health.

Natural background radiation exposure (cosmic radiation, earth radiation given by natural radionuclides present in the environment, food and humans) is about 2.4 mSv per year for the entire planet, with the exception of areas with high natural background radiation (even more than 20 mSv per year in some areas of India, Brazil, Congo, Sweden) due to the massive presence of natural radionuclides [1].

Thus, the additional exposure dose received by most of the population of Europe in 1986 was about half of the natural background exposure, which is a quite low dose, closely to effective dose limit (of 1 mSv per year) supported by legislation for an individual of the population. To be mentioned that the effective dose limit allowed for workers exposed for professional reasons (who work with ionizing radiation in the environment) is 20 mSv per year.

Given the levels of radioactive contamination of the environment in Romania, much lower in comparison with Ukraine, Belarus and Russia, the exposure doses received by our population were relatively low (0.2 to 2.1 mSv in 1986) well below those that could produce significant biological effects on human health. Moreover, studies carried out by the hygiene institutes of Romania did not reveal an increased incidence of congenital malformations in children born between 01.10.1986 and 31.12.1987 compared with the reference group (those born before 1986) [3].

Exposure doses and biological effects post-Chernobyl [2]

Average exposure doses received by the affected people in Ukraine following the nuclear accident were distributed as follows:
- 100 mSv, about 240 000 people participating in decommissioning the damaged reactor
- 30 mSv, about 116 000 people evacuated,
- 10 mSv, tens of thousands of people that continued living in contaminated areas, in the first years after the accident.

It is estimated that the maximum exposure dose can be even with an order of magnitude higher in some areas with massive radioactive contamination from the three countries Belarus, Russia and Ukraine.

In other European countries, the maximum dose was about 1 mSv in the first year after the accident, with a progressive decrease in the coming years. The dose is well below the natural background exposure (irradiation) has a low radiological significance.

Another 200,000 workers who received doses of 0.01 to 0.5 Sv were at increased risk of developing late effects, including cancer that could put their lives in danger.

Of the 600 workers that participated directly in the decommissioning, 134 received doses of 0.7 and 13.4 Sv and develop radiation sickness (ARS – Acute radiation syndrome). Of these, 30 died shortly after the accident [2].

In areas heavily contaminated in the three countries, measures taken to limit radiation exposure have changed the lives of millions of people (returning to homeland, modification of eating habits, restrictions and job changing) to damage health conditions including psychiatric problems.

Thyroid cancer was given particular attention, about 1800 cases for exposed children, which greatly exceeds estimates in the 1986. The cases of leukemia (latency 2-10 years) weren't significantly higher in staff directly involved in decommissioning. The greatest increase in cases of thyroid cancer for children has been reported in the Gomel region of Belarus (near Chernobyl) [7].

In the most contaminated areas of Russia, Belarus and Ukraine there are still values of Cs-137 and Sr-90 easily detectable in water and food; thus, in the Bryansk region (Russia), Cs-137 had values of 90 kBq/kg in predatory fish meat, high value for humans too, up to 50 kBq, which led to estimation of doses ranging up to 1.8 mSv in 1996. These values are well above those detected in Romania immediately after the accident [2].

Ever since 1987, a special monitoring program of about 7 million people affected by the accident has begun: liquidators of consequences of the accident (1986 - 1987), evacuated population in 1986 and established in other areas of the former USSR, residents of areas heavily contaminated with Cs -137, Sr-90 and Pu-239, descendants of the irradiated persons (liquidators, people evacuated), people contaminated with I-131, aged 0 to 18 years during the accident [7].

Epidemiological studies have revealed: an increase in the number of people with psychological problems, number of suicides and overall violent deaths among liquidators and evacuated population due to insufficient information on the effects of ionizing radiation, social dislocation and diminishing quality of life. Only complete epidemiological studies will halt the trend of attribution of increasing incidence of all cancers exclusively to the effects of the nuclear disaster, especially in areas heavily radioactive contaminated [8].

CONCLUSIONS FOR CONSEQUENCES OF THE CHERNOBYL ACCIDENT IN ROMANIA

1. The level of radioactive contamination of the environment in Romania after the nuclear accident in 1986 was relatively similar to that of other central and eastern European states; 10 kBq/m^2 at ground level, with few areas over this value.

2. The main radionuclide contaminants, I-131, Cs-137, Cs-134, even Sr-90 from deposition and aerosols immediately after the accident passed quickly in plants and animals. I-131 showed values close to 1 kBq/kg, Cs-137 and Cs-134 values of several hundred Bq/kg, whereas the Sr-90 was below 10 Bq/kg.

3. Radionuclides Cs-137, Cs-134 and Sr-90 transfer difficult from soil to plants trough absorption, were still detectable in food many years after the accident; radioactive contents fell sharply in 1987 and then steadily, reaching below 1 Bq/kg between 1990 and 2003 in most foods. At the same time, there were somewhat higher values detected in berries, mushrooms and venison.

4. In humans, Cs-137 from 1000 to 2000 Bq gradually decreased, so in 1990 reached about 300 Bq. The annual effective dose decreased from about 1 mSv in the first year after the accident, to below 50 µSv between 1990 and 2000, respectively below 10 µSv between 2000 and 2010.

5. Besides the three heavily radioactive contaminated states (Belarus, Ukraine and eastern Russia), other contaminated European countries reported no biological effects on the population after the accident.

Using direct anticoagulants (DOACs) in cancer and other high-risk populations

Cristina Vârlan[1], Florina Topliceanu[1], Lavinia Bârsan[1], Eduard Dănăilă[1], Mihai Șotcan[1]

Abstract: *The major practical advantage of the direct oral anticoagulants (DOACs), comprising the thrombin inhibitor dabigatran and the factor Xa inhibitors apixaban, edoxaban, and rivaroxaban, over vitamin K antagonists is their fixed dosing without the need for laboratory monitoring. With the recent, rapid introduction of the DOACs for the treatment of acute venous thromboembolism (VTE), clinicians are now faced with various questions regarding the efficacy and safety of these compounds overall and in specific high-risk populations. The collective evidence from 6 large clinical trials involving 27,000 patients has demonstrated that DOACs are as effective as vitamin K antagonists (VKA) in preventing recurrent VTE while being associated with a significantly lower risk of major bleeding. These findings are consistent in subgroups of patients with pulmonary embolism, the elderly, and those patients with a high body weight or moderate renal insufficiency, making these agents suitable for a broad spectrum of patients with VTE. DOACs are also an attractive treatment option in patients with VTE and concomitant cancer, thrombotic antiphospholipid syndrome, or heparin-induced thrombocytopenia, but the currently available clinical data is insufficient to make evidence-based recommendations on the use of DOACs in these settings. Several studies evaluating the efficacy and the safety of DOACs in these high-risk populations are underway.*

BACKGROUND

Anticoagulant treatment of thrombotic conditions dates back to the 1930s and 1940s when unfractionated heparin (UFH) and vitamin K antagonists (VKA) were the first drugs to become available. They proved to be effective in preventing death in patients with venous thromboembolism (VTE), comprising deep vein thrombosis (DVT) and pulmonary embolism (PE), and remained the mainstay of anticoagulant therapy in the decades thereafter. The introduction of low-molecular-weight heparin (LMWH) in the 1980s marked the next breakthrough. These drugs could be injected subcutaneously in fixed doses, which simplified the initial management of acute VTE greatly and opened up the opportunity to treat these patients at home. From that time on, a treatment regimen of initial LMWH followed by long-term VKA for at least 3 months was considered standard of care for patients with VTE.

Recently, within a time span of nearly 4 years, the thrombin inhibitor dabigatran [1] and the factor Xa inhibitors apixaban, edoxaban, and rivaroxaban [2,3] collectively termed direct oral anticoagulants (DOACs), were compared with conventional therapy for

---

[1] Carol Davila University Emergency Military Hospital, Bucharest, Romania

treatment of acute VTE in several large clinical trials. Now that these agents have been approved by the respective regulatory agencies around the world, physicians yet have another treatment option for their patients with VTE. This contemporary DOAC revolution has led to a quickly changing landscape of antithrombotic treatment. Clinicians are faced with various clinical questions regarding the efficacy and safety of these drugs overall and in subgroups of high-risk patients. Therefore, in the present review, we briefly discuss the collective evidence from the phase 3 clinical trials evaluating DOACs for VTE treatment. In addition, we will assess the potential role of DOACs in patients with cancer, the antiphospholipid syndrome (APS), or heparin-induced thrombocytopenia (HIT).

METHODS OF DOAC TRIALS IN THE SETTING OF ACUTE VTE

More than 27,000 patients were enrolled in several randomized clinical trials that compared the efficacy and safety of either one of the DOACs with VKA therapy targeted at INR of 2-3 in the treatment of acute, symptomatic DVT or PE. Importantly, the definitions of recurrent VTE and bleeding were similar across all studies and fallowed the recommendations of the International Society on Thrombosis and Hemostasis (ISTH). Outcome events in all trials were adjudicated by the same independent committee who was blinded for treatment allocation, resulting in a similar objective judgment of recurrent VTE and bleeding. Noteworthy differences between the trials are the use of an initial LMWH lead-in period of 5 days in patients receiving dabigatran or edoxaban, whereas apixaban and rivaroxaban where given as oral monotherapy, and the open-label design of the studies evaluating rivaroxaban opposed to the double-blinding in the other studies.

Recently, we reviewed and summarized the evidence from these phase 3 trials in a meta-analysis [4]. Using these data, we will answer clinically relevant questions to aid the physician in choosing the optimal treatment for his or her patient with VTE. Specifically, we will discuss the overall efficacy and safety of DOACs compared with VKA, differences between dabigatran and the factor Xa inhibitors, and the efficacy and safety of DOACs in high-risk subgroups of patients with PE, elderly patients, obese patients, and patients with moderate renal impairment.

CLINICAL QUESTIONS REGARDING THE EFFICACY AND SAFETY OF DOACS FOR VTE TREATMENT OVERALL AND IN HIGH-RISK SUBGROUPS

Clinical question 1: what is the overall efficacy and safety of DOACs in the treatment of acute symptomatic VTE compared to VKAs?

The main finding of the aforementioned meta-analysis was that DOACs are as effective as VKA in preventing recurrent VTE. Because all trials were designed to demonstrate non-inferiority of DOACs, this should reassure the clinician of the overall efficacy of these agents. Most importantly, the comparable efficacy observed in DOAC recipients was paralleled by a 40% relative reduction in major bleeding compared with VKA. Consistent with this substantial reduction in major bleeding, DOACs were associated with a significant 60% relative reduction in the incidences of intracranial and fatal bleeding, the most feared components of major bleeding. In line with the reductions in major bleeding, patients on DOACs had a 25% lower relative risk of experiencing clinically relevant non-major (CRNM) bleeding. Of note, no significant difference in the incidence of major gastrointestinal bleeding between DOACs and VKA was observed, unlike earlier reports raising concerns on an increased risk of gastrointestinal bleeding in patients on DOACs. In support of this finding, a recent population-based study confirmed a similar risk of gastrointestinal bleeding associated with DOACs compared with VKA in non-atrial fibrillation patients [5].

Clinical question 2: are there any differences between the factor Xa inhibitors and thrombin inhibitors with respect to efficacy and safety?

Although the result of the studies evaluating oral direct thrombin and factor Xa inhibitors are frequently combined, in fact they are two distinct drug classes with important pharmacokinetic and pharmacodynamic differences. Compared to oral factor Xa inhibitors, dabigatran has a lower bioavailability requiring administration as a prodrug, has a longer half-life, and is more dependent on renal clearance. Dabigatran is not hepatic metabolized by the P450 cytochrome system and could therefore be a treatment option in patients with liver disease. In contrast, factor Xa inhibitors undergo significant CYP3A4 metabolism and thus are contraindicated in patients with significant liver impairment. Of note, also among the factor Xa inhibitors there are some differences in pharmacologic properties. Clinicians should take these drug characteristics into account when choosing the DOAC that best suits their individual patient, but they also want to know whether there are any important differential effects between these two classes of DOACs in terms of efficacy and safety. Overall, these are no significant differences in efficacy and safety between dabigatran and factor Xa inhibitors. Hence, the choice for a specific DOAC should primarily be based on drug characteristics (eg, renal clearance), treatment regimen (eg, once vs twice daily dosing), and preference for a LMWH lead-in rather than the efficacy or safety profile.

Clinical question 3: can I prescribe DOACs also to high-risk patients including those with PE, body weight>100 kg, the elderly (ie, age≥75 years), or a moderate renal insufficiency?

The overall favorable efficacy and safety of DOACs in the setting of VTE compared with VKA is reassuring and justifies their use in the general population. However, not all clinicians are confident in prescribing these drugs in specific subgroups of high-risk patients. They may have questions regarding the efficacy of DOACs in patients presenting with PE, have concerns that patients with a high body weight will not reach sufficient drug blood levels putting them in risk of recurrent VTE, and fear that the risk of DOAC-related major bleeding complications may be higher in elderly patients, as well as in those with moderate renal insufficiency given the partial renal clearance of DOACs. The similar efficacy of DOACs compared to VKA is consistent in patients presenting with PE, patients with a body weight >100 kg, patients aged 75 years or older, and patients with a creatinine clearance between 30 and 50 mL/min. Moreover, the overall significant reduction in major bleeding associated with DOACs is maintained in the subgroups of elderly patients and patients with moderate renal insufficiency. Based on these results, DOACs should be considered to be an appropriate treatment option for acute VTE in a broad spectrum of patients.

OTHER HIGH-RISK POPULATIONS WITH VTE

Clinical question 4: are DOACs suited for my cancer patients with VTE?

It is estimated that 20% of all VTE are related to cancer and anticoagulant treatment in these vulnerable patients is often challenging. Cancer patients with VTE are at increased risk of developing recurrent VTE compared to non-cancer patients, but also have a higher risk of major bleeding. LMWH is currently recommended over VKA for treatment of cancer-associated VTE due to its better efficacy in preventing recurrent VTE with a similar risk of bleeding compared to VKA.[6] However, LMWH therapy may be burdensome, particularly in cancer patients that often require indefinite anticoagulant treatment. Because DOACs offer a simple oral treatment regimen without the need for anticoagulant control, they could be an attractive alternative. However, at present, clinicians should refrain from providing these drugs to cancer patients since they have not been compared directly to LMWH. Other concerns are possible drug-drug interactions with antineoplastic agents, in particular P-glycoprotein inhibitors, and the gastrointestinal absorption of DOACs in vomiting cancer patients or those with chemotherapy-induced intestinal mucosal defects. Nevertheless, the subgroup analysis of the 1,500 cancer patients enrolled in the DOAC trials does provide guidance for those situations when LMWH is not an option, for instance when patients are unable or unwilling to take daily subcutaneous injections. Interestingly, in these patients, a possibly better efficacy of DOACs compared with VKAs without an increased risk of major bleeding was observed.[4] It should however be realized that cancer patients in the trials probably had a favorable cancer prognosis compared to the real-world cancer population. Patients with a limited life expectancy were excluded from the trials, as were patients in whom long-term VTE treatment with LMWH was anticipated.

Recently, the pooled results of the subgroup of cancer patients enrolled in the trials comparing dabigatran with VKA was reported providing information on the characteristics of these patients as well as on cancer-prognostic data.[7] Active cancer was defined as cancer within 5 years prior to the VTE diagnosis. Compared with non-cancer patients, the 221 patients were older and had a lower renal clearance. The time spent within the therapeutic INR range of 2-3 was comparable between VKA-treated cancer and non-cancer patients (54.5% and 58.3%, respectively) which is higher than in the CLOT17 (46%) and CATCH (47%) trials. The most prevalent tumor types were prostate, colorectal, and breast cancer and 13% had metastasis. During 6 months follow-up, no significant differences were observed between dabigatran and VKA with respect to recurrent VTE or major bleeding. Detailed results of the cancer subgroups from the studies evaluating apixaban and edoxaban are expected shortly.

Before DOACs become an accepted treatment option for cancer-associated VTE, they have to be evaluated in a head-to-head comparison with LMWH. To this end, an important study comparing the efficacy and safety of edoxaban to LMWH in the setting of cancer-associated VTE has recently been started. One thousand patients will be randomized and followed for the occurrence of one of the components of the combined primary outcome of recurrent VTE or major bleeding. Following observations of a similar risk of recurrent VTE in patients with active cancer and those with a history of cancer, patients with VTE will be allowed to enter the study wither with active cancer or cancer treated within 2 years prior to the VTE diagnosis. Moreover, incidentally detected lower extremity DVT or PE are allowed as an entry diagnosis because treatment and outcome is similar for this group of patients. A last innovative feature of the study is the follow-up time of 12 months, which will provide valuable data regarding the treatment of patients with VTE and cancer beyond 6 months.

In conclusion, DOACs may become an attractive treatment for cancer-associated VTE, but at present LMWH remains the preferred option. Although the results of the trial population with cancer are encouraging, further clinical studies are needed to evaluate the efficacy and safety of DOACs directly against LMWH in this population.

Clinical question 5: can I treat my patients with thrombosis and the antiphospholipid syndrome with a DOAC?

APS is an autoimmune disorder characterized by arterial or venous thrombosis or pregnancy complications in patients who repeatedly test positive for circulating antiphospholipid antibodies (aPLA), i.e. lupus anticoagulant, anti-β2-glycoprotein-1 antibodies, or anti-cardiolipin antibodies. It is estimated that 10% of all patients with VTE have circulating aPLA and these patients are at increased risk of recurrent VTE compared to VTE patients without aPLA. When patients test positive for all three types of aPLA, the risk of on-treatment recurrence is as high as 25% over 5 years. The treatment of thrombotic APS is similar to the treatment of VTE in the general population (VKA targeted at an INR of 2 to 3), but is often extended indefinitely in case of persisting aPLA.

Now that DOACs are increasingly used for treatment of VTE, the question arises whether drugs are effective and safe for VTE treatment in the setting of APS too. From a patient perspective, DOACs may be a significant amelioration in this usually young population for whom lifelong anticoagulation with VKAs and frequent INR monitoring is not attractive [8]. Given that aPLA are prevalent in patients with VTE, the aforementioned DOAC trials in the setting of VTE must have enrolled patients with APS because this was not an exclusion criterion. However, patients were not routinely tested for aPLA and outcomes for the patients with known aPLA have not been reported. Therefore, the current knowledge of the efficacy and safety of DOACs for thrombotic APS is exclusively derived from case series and retrospective cohort studies. These represent a select population of thrombotic APS patients that were switched to a DOAC often because of labile INRs, bleeding on VKA, or logistic problems with INR monitoring.

In a retrospective multicenter cohort study, Noel et al [9] enrolled 26 DOAC-treated patients who had thrombotic APS for a median duration of 3 years. Seven patients had tested positive for all 3 types of aPLA and another 12 patients had lupus anticoagulant. Six of 26 patients received rivaroxaban or dabigatran as first-line treatment, whereas the others had been treated previously with another anticoagulant for 1 to 23 years. During a median follow-up of 1.5 years, 1 patient (3.8%) developed recurrent VTE and in 2 patients (7.7%) a bleeding event occurred that led to discontinuation of DOAC therapy.

However, other authors raised concerns about the effectiveness of DOACs to prevent recurrent APS-related VTE. Win and Rodgers [10] presented 3 thrombotic APS patients developing recurrent thrombosis 6-12 months following initiation of second-line DOAC treatment. The cause of these observations of DOAC-failures is unknown. The recurrence rate in APS patients is high and these failures may have otherwise developed under VKA therapy. Moreover, compliance may have been a contributing factor in these patients who were often switched to a DOAC due to difficulties with their INR control. Alternative explanations may be mechanisms intrinsically related to DOACs or their dosing regimens. For instance, inhibition of a single clotting factor might be insufficient to completely block the thrombotic potential in severe APS patients, or the short-life of DOACs causes the procoagulant stimulus to overcome the anticoagulant effect at trough levels.

In summary, current anecdotal evidence on the use of DOAC in thrombotic APS patients is conflicting. As a consequence, physicians should be careful with prescribing DOACs in these patients until robust data become available.

Clinical question 6: are DOACs a treatment option for preventing or treating thrombosis in patients with heparin-induced thrombocytopenia?

HIT is a complication of treatment with UFH or, less commonly, LMWH and is characterized by formation of antibodies to heparin-platelet factor 4 (PF4) complexes. These antibodies may trigger platelet activation in turn resulting in venous or arterial thrombosis, so-called HIT associated with thrombosis (HTT). A decrease in platelet counts is usually observed 5-10 days after initiation of heparin exposure. In patients with confirmed HIT, cessation of heparin therapy alone is not sufficient to prevent HITT and treatment with an alternative anticoagulant is required. Traditionally, 2 classes of anticoagulants have been used for the initial treatment of HIT: parenteral direct thrombin inhibitors, including argatroban, bivalirudin, and desirudin, and nonheparin antithrombin-dependent anticoagulants, including fondaparinux and danaparoid. Although these drugs are widely used in the treatment of HIT, they have several disadvantages ranging from high costs, low availability, need for drug monitoring, dependence on renal clearance, and the absence of an antidote. DOACs could potentially overcome all of these issues. The biochemical structure of DOACs has no similarities with heparin; hence, interactions with PF4 or heparin-PF4 antibodies are not to be expected. This has been confirmed in preclinical laboratory studies that demonstrated that rivaroxaban, dabigatran, and apixaban [13] do not cross-react with HIT antibodies and do not induce platelet activation in the presence of HIT antibodies. Hence, on theoretical grounds, these drugs could be used to treat HIT. These observations suggest that DOAC are a safe alternative to traditional HIT treatment, but confirmatory studies are needed.

In summary, the clinical experience with DOACs for HIT is currently limited, but they have the potential to become the mainstay of anticoagulant treatment in this setting. They do not interact with HIT antibodies and do not cause platelet activation in the presence of HIT antibodies. Together with their favorable pharmacokinetics, high availability, and lower costs, they could be particularly suited for patients with HIT. The results of the ongoing clinical study have to be awaited before the evidence-based use of DOACs in patients with HIT can be recommended.

CONCLUSIONS

With the recent introductions of the DOACs, clinicians now have multiple therapeutic options for oral treatment of patients with VTE. DOACs are as effective as VKA in preventing recurrent VTE, but are associated with a significant reduction in the risk of major bleeding and are easier to use with no need for dose adaptations. These findings in the general trial population are consistent with those in patients with PE, the elderly patients, heavy patients, and patients with moderate renal impairment, making DOACs a suitable treatment option for a broad spectrum of patients. Whether DOACs can also safely be used in patients with cancer-associated VTE, thrombotic APS, or HIT is currently not proven. Studies are underway to evaluate DOACs in these high-risk populations.

SYSTEMATIC REVIEW

Article received on May 10, 2016 and accepted for publishing on August 19 2016.

Risk factors and quality of life in late-life depressive disorders

Octavian Vasiliu[1], Daniel Vasile[1,2]

Abstract: *Late-life major depression is a high-incidence and difficult-to-treat affective disorder. Diagnosis of major depression in old age could also could be a challenge, due to aspects like (1) there is a higher vulnerability to the stigma of depression in this population, (2) hypochondriac ideation and somatic symptoms are the main symptoms, while depressive disposition or anhedonia are under-reported by such patients, (3) differential diagnosis includes various organic diseases, but also several psychiatric disorders, like neurocognitive disorders, organic affective disorders, drug induced affective disorders etc. Reduction of social relationships caused by retirement and loss of spouse and friends, as well as a decrease of personal income could precipitate or maintain depressive disorders during late-life. Quality of life in patients diagnosed with depressive major disorders is a rarely monitored parameter, although its importance for case management could not be overemphasized. A reduction of life quality correlates with a poorer functional prognosis, persistence of neglected residual symptoms, low adherence to treatment plan etc.*

Keywords: *late-life depression, geriatric depression, quality of life, risk factors, institutionalized population*

BACKGROUND

Late-life depressive disorders have a high impact over patients' quality of life, general well-being, risk of organic diseases recurrence, involvement in daily activities and life expectancy.

Although depression could be perceived as a part of normal process of ageing, this is only a relatively widespread misconception. Adjustment to changes in life style due to retirement, loss of the spouse, death of close friends, financial losses, decreasing of physical capacities etc, should not be confounded with major depressive disorder. Depression has been identified in 17-37% of elderly patients treated in primary care facilities, and 30% of these have a diagnosis of major depressive disorder [1].

Elderly patients are more sensitive to stigma associated with depression and this is a reason for them to declare less frequently than young adults that they have dispositional symptoms during epidemiological studies [2]. Therefore this kind of data should be regarded with caution, as an underestimation of the depression real incidence in late-life is very possible.

Table 1: Risk factors for depressive disorders in late-life population

Risk factor	Overall impact
Bereavement after loss of spouse, a child or other close relatives	Bereavement after a recent loss correlates with depressive symptoms in elderly [5] Elderly bereaved patients seek frequently medical help for their emotional discomfort [6] Most of the depressive symptoms are reported by mothers who have lost a child after a prolonged suffering and in fathers who lost a child by suicide; it's possible that old adults have a lower risk of depression caused by the death of a child than younger adults, possible due to better coping mechanisms [7]
Retirement	People who retired recently have a higher risk for depression than those who continued to work, although self-esteem scores didn't change significantly, as reported by a prospective evaluation during 2 years [8] Depressive symptoms increase when the retirement is sudden and perceived by the subject as being too early or forced [9] There is a reciprocal relationship, as patients diagnosed with depression tend to retire with 1.5 years earlier than those without depression [10]
Income decrease	Women who have lost their spouse have as main mediator of depression financial burden, while widowed males have mainly problems with house holding activities [11]
Interpersonal relationships decreasing	Loneliness was the only factor which correlated with depression scores in 8% of people aged 60-98 who were institutionalized, thus suggesting that loneliness is an independent risk factor for major depression [5]
Lower physical capacity	Old adults with sedentary lifestyle and physical disabilities had a higher risk (OR=2.44) for depressive symptoms appearance than those with good mobility and that were physically active, according to a 8 years follow-up study; the risk maintained high (OR=1.99) in those with low mobility but active life-style, when compared to those who were both physically active and have an intact mobility [12]
Somatic symptoms, pain included	Presence of several organic diseases predicts late-life depression [5] Organic pathologies which associate important pain have a risk for developing more depressive symptoms and a worsening of pre-existing depressive manifestations [13] Quality of life is decreased more in old adults with symptoms like physical pain, because this is associated with limitations in functionality, fatigue, sleep disturbances, depressive mood [14]
Physical or psychological symptoms of patient's spouse	There is a high correlation between depressive symptoms in both spouses: if one has depressive manifestations, there is a high risk for the other to have the same type of symptoms, and this correlation increases in frequency with the patients' age; age difference between spouses has been associated with more depressive symptoms, and those with younger spouses reported more depressive symptoms in 65+ age than spouses with minor age differences [15]
Psychological symptoms, including decrease in cognitive function	Elderly patients (60+) with major depression who have persistent insomnia have a 1.8-3.5 times higher probability to maintain depressive symptoms than those who doesn't have insomnia [16] Depression appears frequently in almost every type of neurocognitive disorder, even in mild cognitive disorder (MCI), and the risk for depression to increase the risk of MCI conversion to dementia is investigated [17] Late-life depression leads to further functional and cognitive decline [18]
Decrease autonomic functioning	Mobility deficits predict a higher risk of mortality and loss of autonomy in elderly patients [14]
Relocation in other area (from city to rural areas, or from his/her own residence into a long-term care facility)	Institutionalization, lower frequency of visits from friends or relatives and less involvement in social activities have been associated with greater risk for late-life depression [5] In institutionalized patients, depression is more common in women who were widow/single, younger or much older than the mean group age, with lower educational background, poor social and economic status, who live alone [20].

Detecting vulnerable populations for depression disorders is an important process if we look at the risk of early death from natural and unnatural causes in patients diagnosed with depressive disorder (71.1 vs. 75.9 years old) and loss of potentially years of life (13.4 vs. 10.2 years) comparative to the non-depressed population [3].

Risk factors for development of depressive disorder in late-life are intricate, with genetic vulnerability, cognitive diathesis, age-associated neurobiological changes, and stressful events, while protective factors are higher education, high socioeconomic status, and involvement in desired activities, inclusive of religious and spiritual nature [4].

Clinical manifestations of major depression in elderly patients has several peculiarities, like denial or dissimulation of feeling sad or anhedonia, but with predominance of somatic complaints, irritability and anxiety, self-isolation, low level of energy and slow movements.

OBJECTIVE

To assess the specific risk factors for late-life depression and to search for impact of this pathology over the patients quality of life, by analyzing data from literature.

Table 2: Quality of life in late-life depressive disorder

Lin J-H, Huang M-W, Wang D-W et al. [21]	Depressed elderly inpatients have less satisfaction and quality of life; female gender, duration of hospital stay, and in-hospital rehabilitation correlated significantly with quality of life scores.
Doraiswamy PM, Khan ZM, Donahue RM, Richard NE [22]	Late-life depression associates significant quality of life impairments in 5 out of 8 baseline SF-36 items; women rated their quality of life as worse than men on physical functioning and role physical; subjects aged over 70 reported lower quality of life on the summary physical component and a trend for higher scores on the mental component of the SF-36
Dombrovsky AY, Lenze EJ, Dew MA et al. [23]	All domains of health-related quality of life except physical functioning improved with successful acute and continuation treatment using paroxetine and/or monthly interpersonal psychotherapy
Hunkeler EM, Katon W, Tang L et al [24]	Collaborative care intervention (including depression care manager, primary care doctor, psychiatrist offering education, behavioral activation, antidepressants, a brief behavior based psychotherapy, relapse prevention geared to personal needs and preferences) was superior to usual care for depression in elderly patients (60+) diagnosed with major depressive disorder regarding quality of life, self-efficacy, satisfaction with care, remission of depression after 12 months
Heiligenstein JH, Ware JE Jr, Beusterien KM et al [25]	Treatment with fluoxetine for 6 weeks in patients over age 60, diagnosed with major depressive disorder, had improvements vs. placebo in all dimensions of SF-36 health status survey; before treatment these patients had lower values in mental health, role limitations due to emotional problems, social functioning, vitality, role limitations due to physical problems, bodily pain- as dimensions of quality of life and health-related dimensions.

METHODS

Main electronic databases (PubMED, EMBASE, CINAHL, Cochrane) were searched using as keywords „old age depression”, „late life depression”, „geriatric depression”, combined with „clinical dimensions”, „quality of life”, „risk factors”, „prognosis”, „evolution”.

All articles were analyzed, including clinical trials, systematic reviews, meta-analyses, case reports, case series, guidelines and editorials.

We formulated the following inclusion criteria for the selected papers: population age over 60; diagnosis of major depressive disorder, organic depression or mixed anxiety-depressive disorder; institutionalized or community dwelling residents; specified statistical method for data processing; risk factors and/or quality of life as specified variables.

Exclusion criteria were: unspecified age of studied population; age under 60; diagnosis of drug induced depressive disorders, or bipolar disorder- major depressive episodes.

RESULTS

According to the analysis of the data from literature, main risk factors for depressive disorders in elderly are illustrated in table 1. Each factor has a different impact over the onset or evolution of depressive symptoms, but these factors appear seldom isolated, therefore it is hard to quantify each variable's impact.

Patients diagnosed with depressive disorders in late-life have various risk factors for this affective disorder, like social events (d.e. retirement, lack of social interaction), psychologic aspects (d.e. bereavement, cognitive deficits) and organic diseases (d.e. somatic pathologies, decreasing of physical mobility). Therefore, it's important to configure a management plan that includes all these factors and adequate monitoring methods, in order to improve depressive symptoms severity, prognosis and risk of relapse.

Regarding the quality of life in depressed elderly patients, we found several studies which are presented in table 2. All the cited trials are randomized and included quality of life and/or health-related quantitative measurements as main or secondary variables.

Although only a small number of trials dedicated to evaluation of life quality in depressed elderly patients was found, we can conclude from the available data that (1) a significant correlation between depression and quality of life decrease was found; (2) treatment, either psychotherapy or pharmacotherapy, could help in resolving both depressive symptoms and alterations in quality of life; (3) several risk factors like female gender, duration of hospital stay, and in-hospital rehabilitation correlated significantly with quality of life scores.

CONCLUSIONS

There are many risk factors that could be correlated with the onset of a new depressive disorder in old age, or with a relapse or recurrence of a previously diagnosed major depression. Some of these risk factors could be corrected and thus patient's prognosis could be improved (d.e. symptoms related to organic comorbidities, like pain, dizziness, or medical aids for visual or hearing deficits), while others could be only monitored and assisted through counseling (d.e. reduced immobility due to untreatable or only partially treatable conditions, lower physical capacity or bereavement).

Quality of life is an important predictor of prognosis in depressive disorders and monitoring the patients' well-being should be more frequently recommended during psychopharmacologic or psychotherapeutic treatment in elderly population. An increased attention should be placed in patients with depressive disorders and risk factors for lower quality of life, like female gender or long duration of hospitalization.

Modern medicine has a new technology: Therapeutic electroporation

Lucia E. Ionescu[1], Diana M. Popescu[1], Gabriela V. Dumitrescu[1], Simona N. Bicheru[1], Marius Necșulescu[1], Viorel Ordeanu[1]

Abstract: *Electroporation is considered a new start-up in the treatment of various tumors; currently, researches are being conducted in order to develop this technology with medical applications. The technique consists in the significant increase in the electrical conductivity and permeability of the plasma membrane of cells resulting from the application of an external electric field. It is routinely used in molecular biology to transform bacteria, yeast, protoplasts and is performed using the electroporators. Currently, the process seems to be a real solution that enables a targeted drug to act with maximum efficiency on cells and tissues requiring treatment, resulting in obtaining a good therapeutic effect without major side effects. Therefore, pharmaceutical companies are trying to demonstrate through preclinical studies the potential efficacy of this technology, succeeding in recent years to achieve important steps in this direction.*

Keywords: *electroporation, therapy, tumor, medical application*

INTRODUCTION

Modern medicine is always looking for new technologies applicable to the diagnosis, prevention and treatment of diseases. Among these, the applications of molecular biology represent a direction of the future, particularly in the treatment of diseases currently considered incurable. Translational medicine applies the new discoveries, in molecular and genetic biology, as well as the techniques resulted from these, for therapeutics based on biology, which gradually replaces therapeutic based on chemistry. For example, by applying electric current at cell level, can be inserted into altered cells, the therapeutic molecules or transfection of genetic material can be achieved.

ELECTROPORATION

Electroporation is the electropermeabilization of cell membranes, which consists in increasing the electrical conductivity and permeability of the plasma membrane of cells, being caused by the application of an external electric field. This procedure is particularly useful in molecular biology in order to insert certain substances in a cell such as a molecular probe or a drug that can induce changes in cell functions or coding DNA [1].

Electroporation is a dynamic process that depends on local transmembrane voltage for each point at cell membrane level. For a certain type and duration of the pulse, there is a threshold of the transmembrane voltage in order to allow the expression of transmembrane electroporation phenomenon between 0.5 V and 1 V. This leads to defining threshold value of the magnitude of the electric field necessary to achieve the phenomenon of electroporation. Only the cells found in an electric field greater than the *threshold* value can be electroporated. If a second threshold is reached or exceeded, electroporation will compromise the viability of the cells, this phenomenon being called *irreversible electroporation* [2].

---

[1] Military Medical Research Center, Bucharest

In molecular biology, the process of electroporation can be used to transform prokaryotic and eukaryotic cells. Bacteria that present a cell wall composed of peptidoglycans for protection, resistance and transport of substances are protected from environmental changes. Based on this characteristic, bringing the bacteria into contact with particular plasmids of interest may have the effect of transferring the plasmid to other bacterial cells, subsequent to an electroporation process by applying several hundred volts over a distance of a few millimeters. Subsequently, the cells must be handled carefully until they divide into new cells that contain new plasmids; this process is about ten times more efficient than chemical transformation [3].

This process is also highly efficient for the insertion of foreign genes in cell cultures and in particular in mammalian cell lines. For example, the process is used to produce *knock-out* mice (transgenic mice in which is inactivated a single target gene for the study of phenotypic characteristics encoded by this) as well as in tumor treatment, gene therapy, and cell-based therapy. The process for the insertion of foreign DNA molecules into eukaryotic cells is known as transfection. Electroporation is particularly effective for transfecting cells in suspension in a cultivation medium using an electroporation cuvette.

Electroporation has proven effective for use on *in vivo* tissues for *in utero* or *in ovo* transfection applications. The adherent cells to the substrate can also be transfected using electroporation, thereby providing an alternative to researchers for the trypsinization of the cells prior to transfection. Electroporation is performed using electroporators, purpose-built appliances which creates an electromagnetic field in the cell suspension, which is pipetted into a glass or plastic cuvette foreseen with two aluminum electrodes on its sides. For the electroporation of bacterial cells, a suspension of about 50 µl is used which, prior to electroporation, is brought into contact with the plasmid of interest. The mixture is pipetted in the cuvette, the voltage and the volume to be applied to the probe are set, and the cuvette is placed in the electroporator. Immediately after electroporation, 1 ml of liquid medium is added to the Eppendorf cuvette /tube and is incubated at a temperature which allows the multiplication of bacteria, to recover the cells and to express **antibiotic resistance**, followed by seeding on plates with nutrient agar.

For electroporation to be successful, the plasmid must be "*free of all salt*" because solutions with high concentration of sodium chloride can cause an electrical discharge (known as arcing), a phenomenon which often reduces cell viability.

For a more detailed investigation of the process, special attention should be given to the output impedance of the porator device and to the input impedance of the cell suspension (e.g. the salt content). Because the process requires direct electrical contact between the electrodes and the suspension, and it does not occur between isolated electrodes, it is obvious that the process requires the existence of electrolytic effects due to mild currents and electric fields [4].

Electroporators are special laboratory equipment that give the possibility to achieve electroporation for multiple samples at the same time, with sets of electrodes specific for cell cultures, such as X2HT Gemini system manufactured by BTX-Harvard. Electroporators can be set to different operating parameters, allowing researchers to optimize the electric field strength depending on the cell type and by the presence or absence of the cell wall [5].

Electroporators have been used on a wide range of cells, including *Escherichia coli* (for transformation) and mammalian cells (neurons, astrocytes, neuroglial, lymphocytes, monocytes, fibroblasts, epithelial and endothelial cells) from humans, mice, rats, and monkeys (for transfection [6].

Physical mechanisms of electroporation

Electroporation allows inserting into the cell DNA molecules, which do not have the ability to passively cross the cell membrane (the lipid hydrophobic bilayer). There are several ways in which changes can be caused to the electric field at the cell membrane level with very different mechanisms and effects. The electroporation advantage lies in the fact that lipid molecules are not altered in terms of chemical and the membrane has the ability to form a pore that will serve as a conductive path through the lipid bilayer [4].

Electroporation is a process with many stages and distinct phases [7]. Initially, a brief electrical pulse of 300-400 mV must be applied for less than 1 ms, which causes changes at membrane level related to the migration of ions in the surrounding solution. Once the critical stage is reached, a local rearrangement on the morphology of the lipids rapidly occurs and the resulting structure is considered to be a "pre-pore" because it is not a good conductor, but quickly leads to the formation of a conductive pore. Most evidence in support of this idea, come from the "flickering" process that occurs at the level of the pre-pores with the formation of hydrophobic regions of approximately 3Å [8].

If this theory is correct, the transition to the conductive pore may be explained by a rearrangement at the edge of the pores in which the lipid ends create a hydrophilic interface.

Finally, the conductive pores may suffer processes of reorganization, expansion or rupture, which can be influenced by various local factors such as the place and the moment in which the change occurs, the mechanical stress and the energy of the lipid bilayer existing at the time of trial [9].

MEDICAL APPLICATIONS

The optimization of electroporation is difficult to achieve, but it has been demonstrated that high voltage electroporation can almost irreversibly destroy the target cells, neighboring cells remaining unaffected. Thus, electroporation can form a new therapeutic approach in the treatment of cancer, cardiac disease and other pathological conditions which require the excision of tissue [10].

A recent technique called **non-thermal irreversible electroporation** has proved successful in the treatment of various types of tumors. This procedure involves the use of small electrodes (about 1 mm in diameter), placed inside or around the target tissue for applying short electrical pulses, repeating at a predetermined frequency and voltage, which increases resting transmembrane potential. As a result, when the applied electricity is higher than the threshold value for the target tissue, forming nanopores in the plasma membrane can become permanent and the cell repair mechanisms of "immortal" cancer cells become ineffective and the cells die.

The procedure is unique, due to the fact that compared to other tumor ablation techniques it does not affect the healthy tissue surrounding the tumor. In contrast, **reversible electroporation** occurs when electricity is applied through the electrodes below the threshold level of the electric field of the target tissue. Applying an electrical energy below the threshold allows the cells to rebuild the phospholipid bilayer and to resume normal operation. Reversible electroporation is carried out in the normal way for the administration of treatments which involve the insertion of some therapeutic molecules (drugs, genes, etc.) into cells. Since not all tissues have the same threshold of the electric field, precise calculations are needed before starting treatment, to ensure operating efficiency.

A major advantage of using non-thermal irreversible electroporation is that when done correctly, as a result of careful calculations made, it affects only the target tissue, while the proteins, the extracellular matrix and some critical structures such as blood vessels and nerves remain unaffected by this treatment. This allows a faster recovery and enables a faster replacement of the necrotic tumor cells with healthy cells. The first successful treatment of malignant skin tumors in mice was conducted in 2007 by a group of scientists (Garcia, Paulo A. & al.), who conducted the complete ablation of the tumor in 12 of 13 mice. They accomplished this by sending 80 pulses of 100 µsec to 0.3 Hz with an amplitude of the electric field of 2500 V / cm, to treat skin tumors. Prior to performing the procedure, the therapist must carefully calculate exactly what should be done and to customize the therapy to the patient needs using imaging (CT and MRI) to create an accurate three-dimensional image of the tumor. This information is very important because one can estimate the tumor volume and decide on the type of therapy, place and angle of insertion of electrodes and applied voltage, sometimes even during the procedure, especially when electroporation is used to treat brain tumors.

The whole procedure is quick (about 5 minutes); the success rate is high and therefore very promising for future treatment extrapolation to humans. A disadvantage would be that the released electricity can stimulate muscle cells causing their contraction, which in some cases can have serious or even fatal consequences. Therefore, a muscle relaxant agent (curare-like compounds) should be used while performing the procedure. The researches conducted so far have been successful, but the taken action must be subject to the existence of a risk when general anesthesia is being used. A recent technique called **irreversible high-frequency electroporation**, uses electrodes to apply bipolar electrical pulses at a high frequency, as opposed to low frequency monopolar electrical pulses. This type of procedure also leads to tumor ablation with the difference that it does not produce muscle contraction and therefore does not need a muscle relaxant agent [11].

Researchers have had success in treating the test animals with multiple tumor types. Even if you are not prepared to routinely apply this technique in the treatment of tumors in humans, non-thermal irreversible electroporation is used in practice for treating cutaneous and subcutaneous tumors. There have also been attempts to treat human cancer of the prostate, lung, kidney and liver. There are still many things to be set in place, on how to damage the animals and especially the man. Kenneth Thompson et al. tested the safety of applying this technique on humans who had tumors in their lungs, kidneys and liver. The treatment was found effective in 71% of cases and, respectively, in 49 patients out of the 69 cases of patients treated was achieved complete ablation of the tumor [12]. The highest rate of success was recorded in liver tumors. The result of this study thus provides encouraging evidence related to the future use of this technology as an alternative method of treating cancer in humans.

Electroporation can also be used for the insertion of drugs or genes into the target cell through the use of short, intense electrical pulses to transiently permeabilize the cell membrane. This procedure is referred to as **electrochemotherapy** when the molecules to be transported are represented by a chemotherapeutic agent or **gene electrotransfer** when the molecule to be transported is the genetic material (DNA) [4].

PHARMACEUTICAL APPLICATIONS

Some pharmaceutical companies have performed surveys on the development of electroporation procedures with the scope of providing a viable alternative to cellular uptake of drugs. This approach is based on the fact that human cells do not allow the free entry of foreign matter through the cell membrane, which results in delay in the operational efficiency of a drug. Therefore, electroporation can be a real solution to allow a drug to act directly, quickly and with maximum efficiency on cells and tissue requiring treatment, resulting in obtaining a good therapeutic effect without major side effects.

Therefore, Inovio and OncoSec tested the effectiveness of this technology and managed in 2013 to achieve important steps in this direction. The results allowed them to also achieve substantial gains: the company Inovio Pharmaceuticals (NYSEMKT: INO had gains of almost 500% and the company OncoSec Medical had gains of 150%. Inovio performs studies using synthetic vaccines, while OncoSec is testing therapeutic agents that are already used during cancer treatment. The company Inovio Pharmaceuticals has developed about 12 "*electroporation pipes*", for the treatment of cancer and infectious diseases. Thus, the tests performed on the H1N1 influenza vaccine developed by the company's specialists have highlighted the protective immune response comparable to conventional vaccines. Also, the SynCon DNA vaccine caused total protection against the infection with the viruses of Ebola and Marburg hemorrhagic fevers [13].

Preliminary studies for both types of vaccine, although in the initial stage, show that these exhibit a strong effect against the spread of these deadly viruses. On June 14th, 2014, Inovio announced that the H7N9 vaccine generated protective antibody HA with a percentage of 100% of the animals tested, and on July 10th, the results obtained from testing the HIV vaccine were published in the Journal of Infectious Diseases. Inovio found that the CELLECTRA system used for administering the Pennvax - B HIV vaccine improved the efficacy of the medicine in the first phase of testing. On July 18th, 2014 Inovio announced that electroporation significantly improves the outcomes of the DNA therapy in terms of stimulating the multiplication of blood elements. Administering with the CELLECTRA system the hTERT DNA vaccine used in cancer therapy and the anti-MERS vaccine has demonstrated that a good immune response has been generated during preclinical studies, improving the survival of patients [14]. OncoSec Medical conducted in preclinical testing centers studies for the treatment of metastatic melanoma, Merkel cell carcinoma (MCC) and cutaneous T cell lymphoma. In the study were included 15 patients with MCC, and so far the company’s electroporation platform has been shown to be safe; in the last check, all patients showed an increase of IL-12 absorbing of at least 100 times, and in some cases up to 1,000 times.

This provides hope in regards to reducing the side effects that occur subsequent to immunotherapy. Also, studies have been conducted on a group of 25 melanoma patients. Were reported complete records for 21 of them and was observed that 38.1% had a favorable complete response lasting more than 6 months and in 61.1% of patients was observed a 30% regression of the tumor. All this led to an increase in the company’s market share by 63%. It is considered that the near future will bring a series of novelties in this field, such as:

- the extension of the studies and obtaining positive results, for more than small populations of patients;

- reporting by Inovio of the data from the Phase 2 Study for VGX-3100 in the treatment of cervical dysplasia, which in Phase 1 has shown good immune response;

- reporting by OncoSec of the final data from the study of melanoma and for the Merkel cell carcinoma;

- presenting plans to launch a study for treating cutaneous lymphoma with T-cells, but also for the initiation of a new research for the treatment of solid tumors;

- OncoSec presenting the company’s plans that expressly foresees combining the electroporation device with the anti-CTLA4, the anti-PD-1 and the anti-PD-L1. As is well known, the anti-PD-1s, particularly, was among the most frequently discussed cancer therapies last year, after Merck and Bristol-Myers have reported incredible data to the American Cancer Society (ASCO). All these led to the idea that electroporation increases the assimilation of some therapeutic agents and reduces side effects, thus making them even more efficient. Therefore, careful monitoring of therapy with anti-PD-1s and the OncoSec plans to expand the researches for the ImmunoPulse platform, finally pursue further researching for this therapeutic agent [15].

CONCLUSIONS

Therapeutic electroporation is a new treatment technology at cellular level. The method is based on the electroporation of the cell membrane which becomes selectively permeable to the therapeutic agents used. *In vitro* and *in silico* experiments are promising and have allowed the insertion of chemical or biological molecules in the target cells. The *in vivo* experiments on laboratory animals have given good therapeutic results, therefore, in the future may be applied to humans. Therapeutic electroporation can become in the near future, an important treatment for oncology, cardiac, infectious diseases etc., envisioning the predominant biological perspective of therapeutics in modern medicine.

The incidence of tracheoesophageal fistulas and it major determinant factors

Bogdan Petre[1], Ioana Oprea[1], Denisa Ghinescu[1], Mirela Bidilică[1], Ovidiu Bratu[1,2], Raluca Petre[3], Cristian Boroș[3], Narcis Tănase[1], Laurențiu Ene[1], Dan Corneci[1,2]

Abstract: *The tracheoesophageal fistula which occurred during oro-tracheal intubation of a patient in intensive care unit is a true challenge both in diagnostic and in therapeutic approach. The best treatment is prevention, by identifying risk factors but especially is important which the mechanism in the occurrence of tracheoesophageal fistula was. The occurrence of this complication in the evolution of hospitalized patients in ICU is accompanied by significant increase in mortality, contributing to negative prognostic. We have started a large multicentric study in April 2016 regarding all patients who required intubation longer than 7 days. The study will finish at the end of 2020. We are looking for a definite conclusion, in this moment we do not have enough data for a conclusion.[1, 2]*

INTRODUCTION

The tracheoesophageal fistula is an abnormal communication between the esophagus and trachea. It can be congenital or acquired. Most of them are congenital with a frequency of 1 to 3500/ 6000 births. In this case usually are associated, or appear within, with other birth defects (trisomy 13, 18 or 21, tetralogy of Fallot, other digestive problems or muscle skeletal VACTERL Syndrome (**V**ertebral anomalies, **A**nal atresia, **C**ardiac defects, **T**racheoesophageal fistula and/or **E**sophageal atresia, **R**enal & **R**adial anomalies and **L**imb defects.). Then, there are the malignant ones which appear in the posterior infiltrating tracheal wall or the anterior wall of the esophagus. The last ones are those acquired, non-malignant [1, 3, 4].

They occur particularly after a prolonged period of intubation with or without mechanical ventilation. Fistula can result from incidents of intubation maneuver, in the operating room but especially in ICU. The first fistula appeared after a prolonged period of intubation and was initially described in 1956 by d'Avignon [2, 4].

Several factors are involved in these serious complications during a prolonged period of intubation. The most important and most discussed about in recent years is represented by the cuff pressure of orotracheal tube. If the cuff is overinflated, it leads to compression on the rear wall membranous trachea, which in time leads to ischemia and necrosis, basically forming an abnormal communication between the trachea and esophagus. Other possible complication of a hyper-inflated cuff is tracheal stenosis or bleeding erosion of a significant blood vessel. Often, both situations can occur simultaneously. The

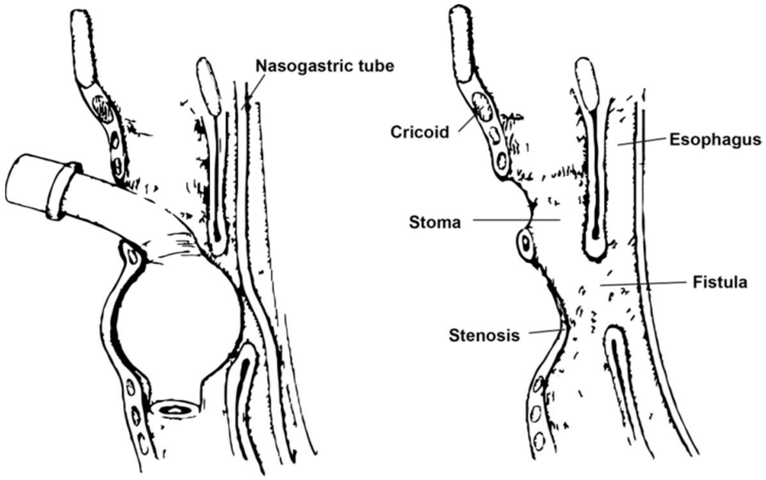
[3] University Emergency Hospital, Bucharest

tracheoesophageal fistulas were more common when the high cuff pressure tubes were used. Once with the use of tubes with high volume and low pressure cuff, the incidence of fistulas has dramatically dropped down. In the international literature the occurrence of these fistulae has a relatively low frequency, of approximately 1% [4, 5, 6].

The widely accepted indication is that the cuff pressure tube should not exceed 25 cm H_2O and the volume should ideally be of 6-8 ml air. More than 10 ml of air should raise the question about tracheal injury. There are data from multi-center studies which have shown dangerously high cuff pressure after patient mobilization. These recommendations are given after multiple multi-center, international researches, but the low pressure cuff has the same danger like the high-pressure ones. If the trachea is not fully secured, then the patient is prone to tracheobronchial aspiration, despite the good and high efficient nursing [7, 8].



© 2016

The tracheostomy does not reduce the risk of tracheoesophageal fistula, the cuff of the cannula can injure the trachea in the same way. If the cannula's material is too rigid, the direct injury of tracheal wall may become possible through angulation [2].

The other factors involved in the occurrence of tracheoesophageal fistula are the presence of rigid nasogastric or orogastric tube, anemia, malnutrition, hypoxemia, anxiety, changing positions in bed, steroid treatment, advanced age, low perfusion from severe shocks [9, 10].

Tracheoesophageal fistula are located usually at the superior half of trachea, and in case of tracheostomy, 1-2 cm below the stoma [10].

The diagnosis of tracheoesophageal fistula is difficult. Suspicion of fistula is based on clinical signs: loss of air from breathing circuit, air on gastric tube, recurrent pneumonia, etc. We can do clinical test by administering blue methylene on the tube, but the diagnostic choice remains the bronchoscopy, images of computed tomography and upper gastrointestinal endoscopy [8, 11].

Treatment is usually surgical; less invasive procedures can be performed particularly for smaller defects, consisting in placing endoscopic stents [12].

PATIENTS AND METHODS

We have started a large prospective multicenter study in two intensive care units, the Central Military Hospital and University Emergency Hospital, Bucharest, Romania. The study started in April 2016 and will finish in the end of 2020.

All patients admitted to the intensive care unit which required orotracheal intubation more than 7 days, with or without mechanical ventilation, will be enrolled. Each observation paper will be attached in a special sheet and will include all the monitored parameters.

The parameters which will be monitored: counting days of orotracheal intubation, the pressure in the tube cuff, presence or absence of gastric tube, nutritional status of the patient, and hemoglobin during hospitalization, necessary of inotropic substances, presence or not of steroid treatment. Bronchoscopy will be performed regularly for early identification of changes of tracheal wall.

RESULTS

The occurrence of this complication in the intensive care unit of Military Central Hospital Bucharest during last five years was zero among the admitted patients (about 1500/year).

From 2,800 patients which were intubated, 1,100 needed tracheoesophageal intubation or tracheostomy more than 48 h. It is obvious that incidence of tracheoesophageal fistulas is inferior compared to actual literature information. So, we are looking forward the results of this study, in this moment the data we have aren't enough for a conclusion.

DISCUSSION

Our study aim is to highlight exactly the incidence of tracheoesophageal fistulas among endotracheal intubated patients in the ICU and their determinant factors.

Early identification of these complications with direct impact on morbidity and mortality of patients is extremely important. Secondary occurrence of pulmonary fistula and subsequent contamination of the lung may results in severe suppurative complication. Prompt treatment, either conservative or surgical, should be immediately applied.

In conclusion, the occurrence of tracheoesophageal fistulas can be lowered by aggressive nursing measures and eliminating/correcting determinants, including days of orotracheal intubation.

CLINICAL PRACTICE

Ankylosing spondylitis and cardiovascular risk – Case report

Daniela Anghel[1], Lucian M. Ciobîcă[1], Silviu M. Stanciu[1], Ciprian V. Jurcuț[1], Gabriel D. Stoicescu[1], Ioana A. Răduță[1], Ancuţa Coca[1]

Abstract: *Introduction: Ankylosing spondylitis (AS) is a chronic progressive inflammatory disease of the axial skeleton and peripheral joints associated with HLA B27 antigen and with the predominance of the male gender (with an average between 20 and 30 years old).*

Case presentation

A 48 years old male patient was admitted to our clinic, having a long history regarding this disease since he was 16.

This patient has switched 3 therapies with anti TNF alpha agents until now, and we hope to obtain a good response for a long time.

During the treatment with Etanercept he presented an acute anterior uveitis which had a good response to therapy.

Conclusion: The ankylosing spondylitis management is complicated when we have the possibility to choose only three anti TNF alpha agents. If a patient does not respond to the first or second agent we are constrained to follow the last one. Therefore the principal problem regarding this special case is that the patient is non responder at the last agent. So the question that arises is witch will be the next therapy for this patient?

INTRODUCTION

Ankylosing spondylitis (AS) is a chronic progressive inflammatory disease of the axial skeleton and peripheral joints – asymmetric.

Its major characteristic is the early damage of the sacroiliac joint, ascending to ankylosis. The incidence is increased for males between 20 and 30 years old, thus most of the patients are associating a HLA B27 antigen. The existence of cardiovascular risk due to inflammatory rheumatic diseases is known for decades but the real significance and therapy designed to control this risk has been recently evaluated.

Systemic inflammation because of inflammatory rheumatic diseases accelerates atherosclerosis and destabilizes plaque of atheroma, contributing to an increased frequency of fatal cardiovascular events such as myocardial heart attacks and strokes. The ankylosing spondylitis cardiovascular events include: aortic insufficiency, heart muscle damage (dilatation/hypertrophy), nerve impulse conduction disorders, pericarditis, and accelerated atherosclerosis.

Anti TNF-alpha therapy leads to a decrease of the disease activity score (BASDAI) and also the nonspecific inflammatory syndrome.

The anti TNF approved drugs which are currently in clinical practice are:

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest

1. Infliximab (*Remicade®*) – chimeric monoclonal antibody anti-TNF alpha;
2. Adalimumab (*Humira®*) – fully human monoclonal antibody anti –TNF alpha;
3. Etanercept (*Enbrel®*) – a fusion protein between the type 2 p75 receptor of TNF and an IgG1 Fc fragment.

CASE PRESENTATION

We present the case of a man, A.I., 48 years old, from urban medium, nonsmoker, having an insignificant family history, diagnosed since 1982 when he was 16 years old with juvenile arthritis.

He came for the last hospitalization, for clinical and biological reassessment, with ankles light arthralgias.

From his medical history we know that the disease has started when he was 16 years, with ankles and knees arthritics, at radiocarpal joints, at bilateral elbows, acute back pain and fever. The patient was diagnosed with juvenile arthritis and treated with Sulphasalazine 6 grams and nonsteroidal anti-inflammatory drugs. Under this treatment he had a slightly favorable evolution with partial improvement of symptoms. After 2 years of treatment disease flares have appeared, therefore the dose of Sulphasalazine at 8 grams/day was increased and a quantity of Methotrexate 7.5 mg/week was also added. After 1 year his clinical and biological evolution became favorable and the dose of Sulphasalazine was reduced to 4 grams/day, keeping Methotrexate and nonsteroidal anti-inflammatory drugs at the same dose. In 1998 he was diagnosed with ankylosing spondylitis according to the New York criteria and the association of HLA-B27 antigen. The patient gave up Methotrexate, the swelling and pain in large joints persisted so we increased the Sulphasalazine dose to 8 grams/day. The patient has annually done physio-kinesiotherapy. In 2009 it was decided to initiate biological therapy criteria (low back pain and morning stiffness, bilateral sacroiliitis grade 4, BASDAI 8.6) according to Guidelines for the treatment of ankylosing spondylitis.

In March 2009, the Infliximab (*Remicade®* 100 mg / fl) 5 mg/kg treatment was initiated. After a loading with Infliximab at 0, 6, 12 weeks, the patient had a clinically and biologically favorable development for 18 months.

Figure 1: Indications of biological therapies in ankylosing spondylitis by therapeutics protocols

Ankylosing spondylitis certain diagnostic according to the criteria of New York 1984:
• Low back pain and morning stiffness more than 3 months, being improved with effort and does not disappear at rest • Movement limitation of lumbar spine in sagital and frontal planes • Limitation of chest expansion • Unilateral or bilateral sacroiliitis grade 3-4 grade 2-4 (imaging criteria). • Diagnosis involves the imaging criteria presence (radiology, MRI) associated to at least one clinical criteria.
Active and severe disease
• BASDAI ≥ 6 for at least 4 weeks • Erythrocyte sedimentation rate > 28 mm/h • C reactive protein > 20 mg/L and 3 x VN (quantitated)
The failure of traditional therapies
•At least 2 nonsteroidal anti-inflammatory drugs continuously administrated for at least 3 months, at maximum recommended doses or tolerated for patients with axial forms • Patients with severe axial do not need a remitting (Sulphasalazine) before the biological therapy • Nonsteroidal anti-inflammatory drugs and Sulphasalazine in peripheral forms, at least 4 months of treatment at the maximum tolerated dose (3 g/d) • Ineffective response to at least one local administration of a corticosteroid injection in peripheral arthritis and/or active enthesopathies, if indicated.
The presence of hip joint damage and extra-articular manifestations are additional factors allowing anti-TNF therapy administration at a lower score of disease activity, with BASDAI ≥4

At the end of the year he suffered an acute infero-lateral myocardial infarction. The patient was hospitalized in the cardiology department, a coronary angiography was performed which revealed a 80-90% anterior descending artery stenosis, to the distal 50-60% left coronary artery stenosis, 80% stenosis in the origin of the AC, 90% oblique median artery stenosis.

The biological therapy was stopped and a surgical intervention was performed with a triple coronary artery bypass graft with autologous saphenous vein.

A carotid Doppler ultrasound was performed showing that carotid vascular system was without hemodynamically significant stenosis. Cardiac ultrasound revealed (left ventricular hypertrophy with anterolateral myocardial contractility low post, left ventricular ejection fraction 55%). Three months postoperatively the biological therapy with *Remicade®* was restarted but the second adverse reactions has occurred (generalized rash, severe hypotension). The patient received Sulphasalazine 6 grams/day, painkiller, intermittent nonsteroidal anti-inflammatory drugs and cardiological medication. Biological evaluation showed a mixed dyslipidemia, associating a grade 1 obesity.

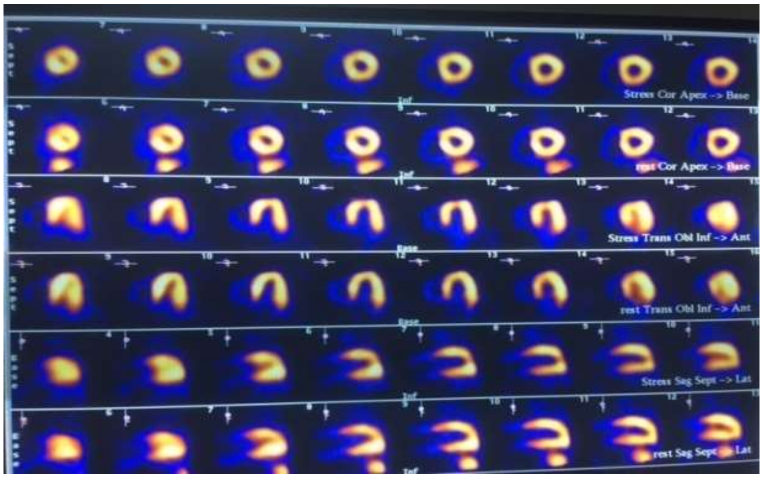
Rheumatic symptoms were significantly exacerbated (peripheral arthritis and low back pain, intense predominantly nocturnal), thus it was decided to initiate therapy with another anti-TNF alpha (*switch*) respectively Adalimumab (*Humira*®). In February 2011 a first dose of Adalimumab – *Humira*® 40 mg/2 weeks sc was administrated.

After 6 months of biological treatment with Humira, the following peripheral arthritis, acute lombalgy and inflammatory syndrome have persisted, BASDAI score was 8.1 and anginous pain occurs during small efforts. The angiography was repeated after which angioplasty was performed. Cardiac ultrasound is performed together with control cardiac stress tests, highlighting a grade 2 mitral regurgitation, posterior mitral ring atheromatosis, hypokinesia in the left ventricle lower part. Our patient had high blood pressure values being diagnosed with a 2 grade essential hypertension, thus instituting a antihypertensive therapy treatment. Therapeutics commission (rheumatologist – cardiologist) has decided to interrupt the biological therapy, considering the patient as being non responder according to the guide treatment ankylosing spondylitis criteria. The patient has continued the background therapy with Sulphasalazine 8 grams/day, pain relievers and cardiological medication.

Persistent inflammatory syndrome associated with peripheral arthritis (*de novo*, costo-vertebral arthritis and intense bilateral talalgia), BASDAI score was 9.1, has imposed a board therapeutic meeting whose opinion was to switch on the last anti TNF alpha, which remained the only therapeutic option, Etanercept (*Enbrel®* 50 mg/week).

Before the Enbrel therapy initiation a whole-body bone scintigraphy was performed (osteogenic lumbar spine and right acetabulum reactions), CT abdominal-pelvic (grade I hydronephrosis left kidney, left kidney chronic pyelonephritis) and TB QuantiFERON test (negative) to exclude a subclinical tuberculosis infection.

Figure 2: Myocardial Perfusion Scintigraphy



After 3 months the patient has presented a favorable evolution with a significant remission of the biological inflammatory syndrome, the peripheral joint tumefactions, persistence of a moderate intensity arthralgia and improvement of overall mobility. The patient was cardiologically reassessed, renal without the evidence of evolutionary elements. An angiocoronarography control was conducted (with 50% restenosis of the anterior descending artery stent), together with a myocardial treacherous tomoscintigraphy ECG synchronized (infero-septal dyskinesia level and decreased left ventricular ejection fraction regional effort – stress left ventricular ejection fraction 49%, resting left ventricular ejection fraction 60 %).

In 2014 the patient experienced an episode of acute anterior uveitis treated with corticosteroids and local mydriatic.

At the last hospitalization in February 2016 the clinical and biological evolution of the patient was favorable, the BASDAI score was 1.6. The treatment include *Enbrel®* the 50 mg/week, Sulphasalazine 1.5 grams/day, and nonsteroidal anti-inflammatory drugs intermittently. The patient is monitored at every 3 months by the rheumatologist and cardiologist and monthly by the family physician evidence the early possible complications.

Particularities of the case

1. Patient with juvenile arthritis, with ankylosing spondylitis evolution and complexes cardiovascular complications;

2. Lack of response to anti-TNF alpha 2 (*Remicade®*- side effects and *Humira®* - non responder);

3. Favorable answer and sustained to the 3rd anti TNF alpha (*Enbrel®*) after 3 years of treatment.

CONCLUSIONS

The introduction of TNF-alpha anti agents in treatment guidelines of ankylosing spondylitis, has revolutionized the therapy of patients with this disease, efficiency confirmed by numerous international clinical trials.

Anti TNF-alpha agents by reducing systemic inflammation creates a real cardiovascular protection for patients with ankylosing spondylitis, aspect highlighted for the case of our patient who has presented progressive cardiovascular events.

The complexity of the presented case is revealed by the associated comorbidities (cardiovascular, ocular, osteoarticular), which responded favorably after two switches of anti TNF-alpha concluding that switch between anti TNF alpha may be an effective therapeutic option in controlling the underlying disease and its complications.

Debut at the young age and association with HLA B 27 antigen are unfavorable prognostic factors for cardiovascular complications.

Interdisciplinary collaboration (rheumatologist, ophthalmologist, and cardiologist) is important for the management of patients with ankylosing spondylitis.

The evolution of this ankylosing spondylitis case is to be followed and the initiation in case of non-responder to *Enbrel®*, with a anti IL type 17 therapy, with sustained international studies having very good results in controlling this disease.

Behçet disease – Case presentation

Lucian M. Ciobîcă[1], Sârbu Iolanda[1], Silviu M. Stanciu[1], Ancuţa Coca[1]

Abstract: *Behcet's disease is a rare and poorly understood condition with multiple systemic manifestations. The disease causes inflammation in blood vessels throughout the body which leads to numerous symptoms that may appear and disappear unpredictable.*

Case presentation

A 33 year old woman was admitted (interned) to our clinic. Her family medical history reveals – multiple strokes (father) and autoimmune thyroiditis (sister).

The onset of her symptomatology was in 2013 and it consisted of fever (39-40 Celsius degrees) sicca syndrome and persistent headaches, recurrent oral and genital ulcerations.

An important event is essential to be mentioned -the patients has suffered an episode of upper gastrointestinal bleeding (hemoglobin has dropped to 2.5g/dl which has led to cardiac arrest-resuscitated).

The lab tests showed: C3 hypocomplementemia, Anti-centromere antibodies (-), anti-b2gp1 antibody (+), lupus anticoagulant (+), U1RNP(-).

We started to administrate cyclophosphamide to the patient, thus his condition has improved after the 2nd dose.

At the 12-month evaluation we were able to see a significant clinical and biological improvement.

Conclusions

In order to be able to talk about "evidence based medicine" for the management of Bechet's disease, a large number of clinical trials is required to provide to the attending physicians the necessary data for diagnosis and treatment.

INTRODUCTION

Behcet disease is a rare condition with a sinusoidal evolution which can affect almost all the organs and human systems, determining multiform symptoms with a variable severity. The medical practitioner has at his disposition a diversity of therapeutic options (from symptomatic therapy to a major systemic immunosuppression); at this moment we can't discuss about fundamental therapeutics protocols and unanimously recognized.

Behcet disease is an inflammatory systemic condition with an uncertain etiology. In the disease pathogenesis both environmental and genetic factors are involved like for the majority autoimmune diseases. This disease has been worldwide described but the maximum prevalence is registered in Middle East, adjacent zones of Mediterranean Sea and Asia

Considering the potential muco-cutaneous, articular, ophthalmic, neurologically, etc. damages, the interdisciplinary collaboration becomes more important. Due to the lack of specific guidelines for the diagnosis and treatment, the therapeutic approach of individuals' cases still remains dependent on the doctor treating experience or on the clinics where these complex cases are monitored.

---

[1] Carol Davila Central University Emergency Military Hospital, Bucharest

CASE PRESENTATION

A 33 year old woman was admitted to our clinic presenting severe muscle weakness and joint pain.

Her medical history has revealed that in the last years the patient was admitted several times in the Infectious Diseases department with persistent fever and severe headaches.

Her family medical history has revealed – multiple strokes (father) and autoimmune thyroiditis (sister).

The onset of her symptomatology was in 2013 and it consisted of fever (39-40 degrees Celsius) sicca syndrome and persistent headaches. As the disease was progressing, our patient presented oral ulcerations, odynophagia, muscle weakness and blindness of the left eye.

The onset of the decreased visual acuity started with the right eye. An ophthalmologic examination has revealed uveitis and chorioretinitis.

Considering an inflammatory demyelinating disease (multiple sclerosis), the neurological exam suggested a cranial magnetic resonance imaging (which has revealed optic nerve edema) and anti-aquaporin 4 antibodies screening (which was negative). The patient treatment has started on Corticosteroids (methylprednisolone in pulse therapy) resulting a slight improvement of visual acuity, persistent joint pains, xerophtalmia.

An important event is essential to be mentioned -the patients has suffered an episode of upper gastrointestinal bleeding (hemoglobin drops to 2.5 g/dl which leads to cardiac arrest – resuscitated).

When the patient was admitted to our clinic the symptoms become more aggressive; the patient present extreme fatigue (with orthostatic intolerance), recurrent oral and genital ulcerations, odynophagia (due to the pain caused by oral and esophageal ulcerations she was not able to solid food or liquids) and blindness of the left eye.

Figure1: Atrophy of retinal layer

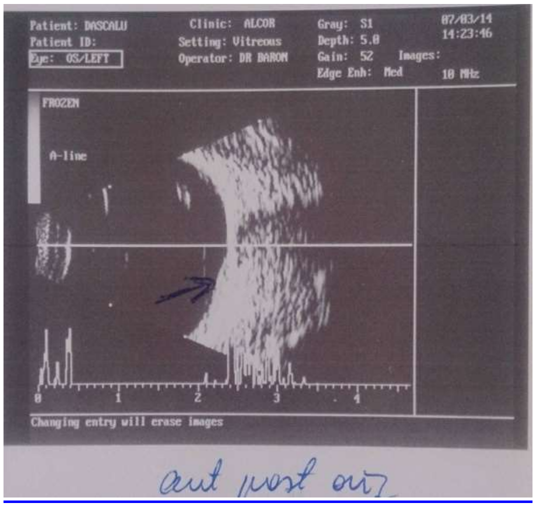

Figure 2: FOS – thicknesses of retinal layer

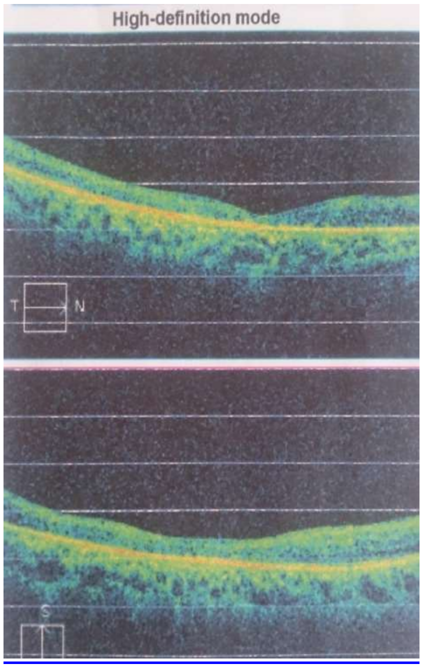

Despite the muscle weakness and severe fatigue that the patient suffered from throughout this whole period, muscle enzymes was never elevated.

Nevertheless we continued our investigations with an electromyogram. The EMG showed acute polymyositis aspect and sensory polyneuropathy lesion.

Then neurological exam showed spastic paraplegia, left brachial plegia and visual acuity loss. The brain MRI revealed a lacunar ischemic stroke in the vertebrobasilar territory.

The ophthalmological exam showed optic nerve atrophy.

We were facing with a patient, having a chronic, inflammatory multisystem condition of unknown etiology. The blood tests revealed nothing but a persistent inflammatory syndrome (ESR = 80-100 mm/h); the immunology tests didn't provide enough information either (C3 hypocomplementemia, Anti-centromere antibodies (-), anti-B2GP1 antibody (+) lupus anticoagulant (+), U1RNP (-), anti-aquaporin 4 antibodies (-) HLA B51 (-), Leiden V factor (+), ANA (+).

However we were in possession of his clinical examination highlights: chronic fatigue, recurrent mucosal ulceration, neurological symptoms, bilateral posterior uveitis, inflammatory arthritis various symptoms that we were able to identify as features of Behcet's disease.

By the time an accurate diagnostic could be established, the patient had already suffered some severe life threatening complications: upper GI bleeding with severe anemia that led to cardiac arrest, severe sepsis caused by infected decubitus injuries and medullar aplasia caused by high dose of immunosuppressive medication.

Behcet disease – generally accepted therapeutic objectives:

1. It's essential having a clear diagnostic and well founded as well as a clear setting of a lesional exact balance, with the progressive potential appreciation of the identified lesions;
2. The remission induction and maintenance;
3. The prevention of irreversible organs lesions (for example the ophthalmological one), which tends to appear early, especially in some problematic groups like young men;
4. The articular and muco-cutaneous exacerbations prevention can significantly improve the quality of life;
5. The multisystem involvement imposes for most cases interdisciplinary implication.

We want to underline the importance of having an accurate and precise diagnostic before starting a treatment, but in this particular case, a rapidly evolving disease worsened by the upper mentioned events, we decide that it was extremely necessary for the patient to start a remissive treatment. We initiated a moderate dose of cyclophosphamide (800 mg – 15 mg/kg bolus intravenous) and a low dose of oral corticosteroid (methylprednisolone 8 mg).

A significant improvement was observed after the second course of cyclophosphamide. The patient has regained the strength and muscular tonus, neurological symptoms has disappeared and she did no longer mucosal ulcerations.

Although the inflammatory ocular symptoms were suppressed, the significant loss of visual acuity persisted (it was caused by initial optical neuritis).

At the 12-month evaluation we were able to see a significant clinical and biological improvement. The patient is now able to do her daily activities therefore her lifestyle has improved.

The brain MRI shows normal brain parenchyma, normal vascular structures and normal blood flow.

Ophthalmological exam: minor restant vitrean abnormalities.

CONCLUSIONS

In the past decade we have witnessed a significant improvement in the therapeutic approach of Behcet's disease by optimal use of the old available drugs and also by the development and clinical use of new therapeutic solutions.

Behcet's disease still remains a multidisciplinary challenge for attending physicians.

Available data in the medical literature consists mainly in clinical cases and series of clinical cases with a limited statistic value.

In order to be able to talk about "evidence based medicine" for the management of Bechet's disease, a large number of clinical trials is required to provide for the attending physicians the necessary data for diagnosis and treatment algorithms.

VARIA

In memoriam – Cristian Babalâc (1954-2006)

Dan Mischianu

I am absolutely convinced that you have never wondered what the etiology of the *ferpar* word is.

The Romanian *ferpar* has its origin linked to the French "fair-part", which, according to the dictionary means a letter "announcing birth, engagement, marriage or, most often someone's death". The above lines are not intended to be a late *ferpar.*

These lines are supposed to bring back the memory of an absolutely exceptional man, a thorough man and a fighter, a true military doctor - Col. Dr. Cristian Babalâc (1954-2006), my University colleague. I also hope that these lines will make you realize that time passes quickly destroying everything on its way.

And time, a decent gentleman for some, covering us with a veil of forgetfulness, time "has a bad habit of being irreversible", as we learned from Octavian Paler.

Our desire is to present the portrait of the man, the military doctor, the professional Cristian Babalâc, because Dr. Cristian Babalâc was – and "to be" in the past tense sounds so sad! – a devoted man and practitioner that always proved an absolute professional availability.

My group colleague and my friend, Dr. Cristian Babalâc was born in Bucharest, on 13 January 1954 on Teodosie Rudeanu street, near North Railway Station, a few hundred meters from the Institute of Military Medicine, the place or "origin" of our emergence, the ones from yesterday, today and future serving Romanian military medicine.

Graduated from High School "Ion Neculce" Bucharest (1973), Faculty of Medicine Bucharest (1979), Doctor of Medicine with the thesis "The value of laser in the surgical treatment of soft part tumors" (1997), specialist doctor in Orthopedics and Traumatology (1989), Senior researcher (1990), consultant in Orthopedics and Traumatology (1995).

He participated as a member or responsible at research contracts, guided numerous diplomas and internships, conducted/aided the full range of orthopedics – traumatology procedures, 15 patents and 7 innovation patents for different medical devices: gurney for the transport of traumatized, forearm electronic prosthesis controlled by sensors, bioelectronic prosthesis for superior limb, immobilizer and transportation device for polytrauma patients, external bipolar monoplane fixator, semicircular external fixator, circular external fixator, universal external fixator, grapples for osteotomy. He introduced "CO_2 surgical laser treatment in musculoskeletal limb tumors" for the first time in the country.

Published the treatise: "Laser in the treatment of musculoskeletal diseases" (co-author) Military Publishing House Bucharest (1999), "Course of emergency and disaster medicine" (co-author) MTM Publishing, Consult Publishing (2003), 147 (20 as first author) communicated papers at congresses, conferences, symposiums in the country and abroad, 28 articles (4 as first author) published in journals: "Journal of Military Medicine", "Journal of Orthopedics and Traumatology", "News Update", "Balkan Military Medical Journal", a member of SOROT – Romanian Society of Osteoporosis Treatment, Romanian Society of Laser in Medicine and Biology, Romanian Association of Military Physicians and Pharmacists.

I knew him as a student and we operated together as specialist surgeons. Dr. Cristian Babalâc was a hard worker by definition, an absolute perfectionist, continually dissatisfied with his achievements – although he managed to accomplish everything he undertook, a deep thinker, a cerebral man, a genuine family man.

He was particularly pleased with the silence at home, the achievements of his wife, the distinguished Head of Hospital Pharmacy of "Prof. Theodor Burghele" Hospital – Ms. Pharmacist Gabriela Babalâc, and the professional accomplishments of their son – Cătălin Babalâc.

Col. Dr. Cristian Babalâc was a "serious man", a professional of orthopedics and traumatology of the Central Military Hospital. Nevertheless, medicine is very often defeated by disease severity.

I confess that I had a sense of absolute helplessness when I was near the bedside of Dr. Cristian Babalâc!

Lack of health, the implacable decline, and the mortal character of all beings – but most of all those close to our soul – are almost unapproachable subjects. As I was writing these lines I was overwhelmed by bleak thoughts.

My intention was only one, to restore the memory of those who knew and valued him, a decade after his passing, the luminous figure of Dr. Cristian Babalâc, although "slightly frown as a result of the multitude of his thoughts".

Leaving us ten years ago after unimaginable suffering, I think Dr. Cristian Babalâc kept one hope in his noble and good soul: maybe better is yet to come!

May God bless his soul!

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine*. Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related “mini-series” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication’, as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must

comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database.

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

WELCOME ADDRESS

Constantin Ștefani

Col. CONSTANTIN ȘTEFANI
Chief of the Medical Directorate
of Romanian Armed Forces

Dear Generals, Admirals, distinguished guests and colleagues,

As the Chief of the Medical Directorate of Romanian Armed Forces, as well as the Head of Romanian Delegation at the 21st Balkan Military Medical Committee Congress, it is a real honour, but also a pleasure to welcome and host you in Bucharest, the capital of Romania.

For us, people destined by history to live in Balkans, the Congress of BMMC, has already acquired a well deserved successful tradition, being an opportunity of approaching the many-sided military medical issues. Together with our colleagues from Albania, Bulgaria, Greece, Serbia and Turkey we have been contributing to the increase of the prestige of this reunion and of its scientific periodical. I am sure that Romanian branch of BMMC will succeed in continuing the best achievements of the previous edition.

In a constantly evolving international environment, we all have numerous issues and perspectives to share and coordinate within the medical community and many questions are raised for many nations but, among these, one is particularly relevant: how to maintain the high level of professionalism reached by military medical personnel. The main topic of this year edition "Balkan Military Medicine – Future challenges" is not only "Food for thought" but an opportunity to exchange ideas and knowledge on Military Medical topics, which is of great importance and value for all of us, considering the present geo-political circumstances in our area and in the world.

In the hope that the congress we are about to commence will be an outstanding example of true scientific, ethical and friendly spirit, I welcome you in Bucharest, a city with more than 800 years of history, once known as the "Little Paris". For those who are for the first time in Bucharest I do hope they will enjoy it and for those, who have been before, to experience new places the capital of our country is willing to offer.

Yours sincerely,

Col. Assist. Prof. Constantin ŞTEFANI, MD, PhD
Chief of the Medical Directorate of the Romanian Armed Forces
President of 21st BMMC Congress

ORAL PRESENTATIONS

OP session 1 – Military medicine

EXPLOITING STRATEGIES OF IMPROVING HUMAN PERFORMANCE FOR MILITARY OPERATIONS

Radu Hertzog

During military operations, the war fighters are exposed to several threats. CBRN agents, blast related events, extreme and austere environments, lack of family, stress and emotional shock jeopardize health, protection, performance and even human condition. Many medical approaches or technologies have been developed or proposed for human performance optimization (HPO), human systems integration (HIS) and human performance enhancement (HPE) in order to support sustainability and survivability as well as to improve combat readiness and effectiveness. The presentation covers few aspects of animal kingdom to understanding of biological underpinnings of high level performance. Nature is providing us an unlimited source to discover bio-tech solutions to counteract the threats that could affect the life of our soldiers.

MILITARY INFORMATION SUCH AS SPECIFIC IN NATURE AND USE INFORMATION

Chobanov N., K. Hristova, S. Kolev, K. Paskalev

PURPOSE

1. Defining the place of military medical information to the general flow of information that serves military science.

2. Determine the purpose and addressees of the information that is gaining SRLMMI.

3. Participation in the creation of a network for the exchange of military medical information.

MATERIALS AND METHODS

1. Materials – NATO standardization documents: Allied Joint Medical Doctrine (AJP - 4.10) and Allied Joint Medical Doctrine for Medical Intelligence (AJMedP - 03); Doctrine for medical insurance. National publication of the Armed Forces of the Republic of Bulgaria (NP-4.10); collections, manuals, lectures and publications of SRLMMI.

2. Methods – systematizing, analyzing, evaluating and interpreting information.

RESULTS

1. Promotion of the mission, strategic goals and objectives of SRLMMI in the short and long term.

2. Creating conditions for future sharing unclassified products conducted by military medical intelligence structures with similar aims and purposes.

CONCLUSIONS

1. Identify hazards to health and life of soldiers during the preparation, implementation and after implementation of missions outside the Republic of Bulgaria is important for successful implementation.

2. The dissemination and exchange of classified military medical products conducted by intelligence structures with similar aims and purposes increases the efficiency of their operations.

ANALYSIS OF THE COST OF MEDICINES AT THE MILITARY MEDICAL ACADEMY

Virsavia Vaseva, Ventsislav Mutafchiiski, Rumen Popov, Lyubomir Aleksiev, Nikolay Petrov

Introduction: Facing conditions of market economy and financial deficits each health manger is challenged to provide cost-effective functioning of its entrusted hospital. In the structure of the treating costs, medicines take leading position, according to leading authors, their share reaches 40% of the total cost. For this reason, introducing scientifically based and cost-effective strategy for analysis and control the costs of medicines proves extremely relevant.

Aim: To analyze the use of medicines at the Military Medical Academy and to propose a model for control.

Material and methods: We used data from Hospital Information System and Financial Department about received income from the National Health Insurance Fund and expenditure on medicinal products in MMA in 2014 and 2015. In 2015 the system for control of medicines spending was introduced. We compared the results of the 2 years. A comparative analysis was made on quantitative and qualitative criteria of medical services for 2014 and 2015. The share of revenue from the NHIF and the cost of drugs to all clinics was calculated. A relative ratio income/expense is calculated, as results are processed by comparative analysis.

Results: Our study shows that in 2015 revenues of NHIF exceed those of 2014 by 3% and the cost of medicines in 2015 decreased by 33% compared to 2014 as the quality of medical services retain their values. The share of the medicine cost to the price of the clinical pathways in 2015 decreased by 7% compared to 2014. For surgical clinics average rate of cost of drugs is 9% and 12% for therapeutic. Surgical clinics have better relative index income/expense than the therapeutic.

USE OF THE ELECTRONIC HEALTH RECORD FOR IMPROVEMENT DISEASES CONTROL IN BULGARIAN ARMED FORCES

Petkov Assen, Valchanova-Stoykova Lubomira, Alexandrov Alexandar, Aleksieva Ivanka, Popivanov Ivan

Based on oral interviews conducted with medical advisers of Logistics Directorate - MoD, Joint Forces Command, Land Forces, Air Force, Navy and doctors from major military units, the authors found the most common reasons for hiding information on changes in health status of military personnel and civilian employees in Bulgaria Armed Forces: concern of dismissal due to unfitness, ethical concerns, discomfort of commanders and colleagues, ineligibility for certain positions, restrictions for participation in missions abroad. The impact of those reasons on the individual and group security in the permanent garrisons and on missions is analyzed.

Based on published till now data from the Ministry of Health and information from the authors about the project “Electronic Health Record” (eHealth record), the authors explore the possibilities of access to health information by military doctors for each serviceman and civilian employee in Bulgaria Armed Forces. The aim is strict control of morbidity and prevention of threats to personal and collective security in both Armed Forces and society. Fundamental ethical and legal problems of access to the eHealth records are analyzed and well-grounded proposals for regulatory amendments are made.

INFORMATION SYSTEM FOR AUTOMATING AND MANAGING PROCESSES IN THE MILITARY MEDICAL ACADEMY

Anna Krasteva, Georgi Yanchev, Rumen Popov, Virsaviya Vaseva

The information system GAMMA HIS possess every module needed for automating and managing the processes at a medical facility.

Military Medical Academy has the experience of creating and implementing medical software solutions for achieving automation and optimization of the processes in outpatient, hospital and para-clinical activities related to the collection, processing and storage of medical statistics.

Main directions of our activity of the Military Medical Academy are:

- Development and implementation of application software in the field of health
- Development of information systems for the needs of hospital care
- Consulting and training of staff in hospitals in the structure of MMA
- Operational maintenance of embedded systems

The range of software products in GAMMA are integrated into a single system, but can function independently on their own. All statements and specifications of software products comply with the requirements of The National Health Insurance Fund (NHIF) and the Ministry of Health, as well as the existing regulations under the Accounting Law. The product GAMMA CODEMASTER is intended to register outpatient and inpatients in hospitals and outpatient medical care. The program keeps the most important data on enrollments, it allows economic analysis and preparation of statistical reports.

The purpose of the program GAMMA MULTILAB is the implementation of automated management of activities related to the process of registration and control of paraclinical services, to store the results and their connection to the electronic medical record of the patient. The product supports a barcode labeling of specimens. Related to system analysts will automatically transfer data and after validation are available for the recipients. The program meets the requirements of the NFC for software labs.

The software Gamma Store - "Hospital pharmacy and warehouse" is designed for automated maintenance of records in pharmaceutical and other warehouses of hospital units that are providing supply and dispensing of medicines and materials to the units of hospitals. The system allows the organization of the work of many warehouses in the health facility with sub warehouses for different types of materials: drugs, supplies, sanitation, food and more. Ordering of medicines and materials can be carried out electronically. The system supports restricting the visibility of availability and prices.

The software GAMMA PHARMA is designed for automated maintenance of records in hospital pharmacies and pharmaceutical warehouses ensuring supply and dispensing of drugs for bedridden patients in inpatient health establishments and other units of hospitals. The program has the ability for monitoring the supply of drugs in competitions and control correspondences between the contract and delivery prices, as well as set the order for delivery of drugs to a supplier.

MEDICAL INTELLIGENCE ORGANISATION IN ALBANIAN ARMY FORCES

Kukeli Edlira, Muhameti Rushan, Duraku Kujtime, Reso Elton

Introduction: Medical Intelligence is a main factor in medical support planning and Medical Force Protection. Medical Intelligence Doctrine should be adapted and implemented in multinational operations conducted in the NATO- lead operations. Main principals, MI cycle and its organisation in Albanian Army Forces play an inportant role in assesment of operational risk.

Objective: The assessment of troop’s healthy risks, preventive measures implementation, support medical services management in missions abroad.

Material and Methods: The descriptive study was conducted in the period of time 2010-2011.The study sample included military contigents redeployed back home from abroad missions. The data was collected from medical records of “Trauma University Hospital”.

Results: This study was conducted at a military contingent (of 120 solders) with mission in Chad. There were identified 10 cases deployd back home with infective disease (malaria). Medical Intelligence is neccessary in operational planning and provides medical information for geografic factrors (clima, flora and fauna) endemic and epidemic deseases, enviroment, toxic, industial risks and taken measures related with Weapons of Mass Destruction (CRBN). Albanian Medical Service Structures lead and cordinate the organisation, planning and medical controls for medical force protection. Albanian Preventive Medical System included Health Inspectoratet that cordinates the medical activity and Military Medical Unit as a specialized institution for health inssurance effectives.

Conclusion: Medical Intelligence has an important role for medical preventive measures, immunisations, healthy education and troop’s medical evaluation in mission.

THE ROLE OF THE BULGARIAN MILITARY MEDICAL TEAM IN THE EU TRAINING MISSION IN MALI

Kesov Georgi, Svetlin Nikolov, Alexiev Lybomir, Karakanov L., Petrov Nikolay, Mutafchyiski Ventsislav, Popivanov Georgi

Introduction: Since 2013 by decision of EU a training mission was established in Mali in order to increase the preparation of the army and to improve the anti-terroristic response. Since its establishment ten Bulgarian military medical teams with 40 medics (20 doctors) have been participated. The purpose of the work is to present the specific tasks of the mission, the most common morbidity, security issues, climate characteristics and the costs.

On the background of the increased Islamic activity in the region this mission has a growing responsibility and significance. It requires specific military medical training of the participants. The close collaboration between medical teams (Role 1 and Role 2) in the training bases is a prerequisite for successful work of the team.

CONCERNING CREATING A STRUCTURAL MODEL FOR DETERMINING THE CROSS-BORDER ENVIRONMENTAL SECURITY ALONG THE BULGARIAN-ROMANIAN BORDER

Hristova Krassimira

PURPOSE

1. Formulation of problems in cross-border environmental security.

2. Theoretical studies to create a structural model for determining the cross-border environmental security along the Bulgarian – Romanian border.

MATERIALS AND METHODS

1. Materials – Transnational program "Danube 2014 to 2020"; „Cross-border program between Romania and Bulgaria for the period 2014-2020”.

2. Methods – systematization, analysis, evaluation and interpretation of available information.

RESULTS

1. New structural model by which to reflect the time and phases of the development of cross-border risks and threats.

2. Formulation of future researches on cross-border risks and criticality.

CONCLUSIONS

1. Cross-border environmental hazards are appropriate to define hypotheses as to their substance.

2. Cross-border environmental threats are a combination of information about the quantity, quality and composite indicators of all the constituent system components.

A SPECIAL POPULATION: PREGNANT WOMEN IN ARMED CONFLICTS

Karasahin K. Emre, Fidan Ulas, Alanbay Ibrahim, Kinci Ferdi, Yenen Mufit Cemal

OBJECTIVE: To investigate the possible effects of war on pregnant women and to delineate the basic healthcare standards for caring pregnant women in armed conflicts.

MATERIAL AND METHOD: An internet research was made using the keywords of “pregnancy” “war” “armed conflict”, “refugee” and “conflict”. It is understood that there is either not much data on the topic or the conflict zones were too busy or deprived for a reliable data to be presented.

RESULTS: Obstetrics can present a large health problem in case of a war. Despite the difficulties of war, high-risk pregnant women could be properly identified and could be referred to a more sophisticated center if cooperation with other (either governmental or non-governmental) organizations could be provided. Resources can diminish fast in cases of mass casualties or high number of people fleeing armed conflict zones. Small and efficient obstetric teams could be set up with mobile ultrasound, or cardiotocographs may be helpful. Basic laboratory elements for urinalysis and hematocrit are desirable. Normal delivery with as little cesarean as possible should be aimed.

CONCLUSION: Although there are numerous guidelines on management of pregnant women in disastrous states, the war situation can be quite different. Medical personnel should be ready to adapt to rapidly changing conditions, such as the weather, advancing hostile forces, the triage priorities, availability of surgical approaches etc. The medical personnel should be protected by solid legal approaches in order to be immune to malpractice cases due to the unforeseen outcomes in obstetric management in war zones. Neonatal outcomes cannot be predicted, and the survival of mother and the neonate may supersede the long term outcomes. The medical personnel should also be psychologically prepared and supported to complete the mission successfully.

A WAR SURGEON: CAPABILITIES AND EDUCATION

Harlak Ali, Kaymak Sahin, Eryilmaz Mehmet, Coskun Ali Kagan, Lapsekili Emin, Ersoz Nail, Unlu Aytekin, Zeybek Nazif, Kozak Orhan

OBJECTIVE: This study aims to discuss the optimal capability of a war surgeon and his educational program. The main mission of military medicine is to threat wounded soldiers.

The War Surgery can be defined as advanced surgical management of war wounds. In daily surgical practice every surgeon works in his special area. For example general surgeons perform usually gastrointestinal operations. They don’t interest in a thoracic pathology. If necessary a thoracic surgeon can participate to the operation. But military trauma causalities have usually complex injuries and their initial treatments are made in a field hospital with limited conditions. A war surgeon must have basic skills for the stabilization of wounded soldiers.

MATERIAL AND METHOD: This study evaluates the wounded compartment of causalities from a military conflict and the role of doctors from different specialties. We have tried to make a conclusion about the basic capabilities of a war surgeon. We also compared our training program in war surgery with the clinical practice.

RESULTS: Duration of war surgeon training program in Gulhane Military Medical Academy is two year after general surgery residency. In this period a war surgery fellow works 13 months in general surgery, 3 months in thoracic surgery, 2 months in orthopedic surgery, 1 month in plastic and reconstructive surgery, 1 month in radiology department. In the latest military conflict, the distribution of wounded compartment and distribution of surgical specialist which participate to the treatment were as fallows: cranial 10 %, facial 14%, neck 4%, thoracic 8%, abdominal 7%, pelvic 6%, extremities 54%, vascular 28%.

CONCLUSION: The results show that a war surgeon must have basic knowledge about orthopedic, vascular, abdominal, thoracic, cranial surgery.

CAN BLUE OCEAN STRATEGY BE APPLICABLE IN MILITARY HEALTHCARE INSTITUTIONS?

Ugur Ugrak, Ugurluoglu Ozgur

OBJECTIVE: As we know, Blue Ocean Strategy can be defined as a new strategy without any competition. In this study, we aimed to analyze of applicability of “Blue Ocean Strategy” in healthcare sector including Military Healthcare Institutions.

MATERIAL AND METHOD: All publications reached in literature surveying with keywords “blue ocean strategy”, “healthcare”, “healthcare management”, “hospital”, “health” and various combination of all were analyzed in context of this study purpose.

RESULTS: Military Hospitals in Turkey have faced with competitive market after starting giving healthcare service to public. Competition is important, however, institutions focusing on competition strategy might skip more crucial strategic aspects. Blue ocean strategy, contrary to traditional rules, doesn’t use competition as a comparison point, instead, aims at reaching untapped markets with creating new value for both themselves and consumers. Blue ocean strategy claims that with tools such as “strategy canvas” and “four action framework”, it can make competition irrelevant and get reached markets in which new demands exist. According to literature review “Blue Ocean Strategy” could be applied successfully in various sector. Even, Malaysia accepted “Blue Ocean Strategy” as a national strategy. Successful example of Blue Ocean Strategy were also seen in healthcare sector.

CONCLUSION: For Military Hospitals, which have been faced with competitive markets, Blue Ocean Strategy is thought to provide useful tools to make competition irrelevant and has a potential to lead those institutions to untapped markets in which new demands exist. Additionally, it is thought that “Blue Ocean Strategy” might be useful to determine unnecessarily focused factors in Military Health Care System, which are complex and highly specialized.

OP session 1 – Microbiology, clinical research and studies

A NEW EXPERIMENTAL INVASIVE MODEL IN THE TREATMENT OF GASTROOSEPHAGEAL REFLUX: IMPLANTATION OF ENDOSCOPIC STEM CELL INTO THE LOWER ESOPHAGEAL SPHINCTER

Caliskan Bahadir, Kantarcioglu Murat, Gunal Armagan, Demirbag Suzi, Bagci Sait

INTRODUCTION: Gastroosephageal reflu disease has an incidence of 23% in Turkey. Endoscopic treatment modalities are used commonly. In this study we endoscopically implantated the stem cell derived from female endometrial tissue to rabbits low esophageal sphincter (LES), observe the differentiation to muscle cell in this area and the effect of this procedure to sphincteric pressure

MATERIAL METHOD: Stem cells 1x106 implantated to 10 rabbits (Group 1) and % 0.9 NaCl implantated to ten rabbits (Group 2). Rabbits LES pressure were studied before implantation and 3 weeks later. On day 21 lower esophageal sphincter dissected.

RESULTS: Histopathological examination of group 1 showed GFP expressing cells in the lower esophageal sphincter of the rabbits. It has been observed that these cells express MYO D protein that play a key role in muscle differentiation and factor MHY-2 which contributes to the formation of myocytes. When compared to controls, increase in LES pressure in the stem cells-implanted group was obtained.

DISCUSSION: Endoscopic human endometrial progenitor stem cell implantation to LES leads to the differentiation and an increase in sphincter pressure. Our findings suggest that, implantation of autologous stem cells, using the natural human cells in selected gastroesophageal reflux disease patients with LES failure can be a new invasive endoscopic therapeutic model.

MOLECULAR STUDIES REGARDING SOME TICK BORNE – PATHOGENS IN ROMANIA

Alexandru Vladimirescu, Victoria Gabriela Dumitrescu, Lucia E. Ionescu, Valentina Elena Moraru, Marius Necşulescu, Simona Bicheru, Diana M. Popescu, Doina Daneș, Stelian Bărăităreanu, Marius Ciocănău, Valeria Purcărea-Ciulacu, Gabriela Nicolescu

Our studies undertaken between 2006 – 2015 have shown that the most frequent species of ticks in Romania is Ixodes ricinus. Three Romanian counties were selected as ticks sampling sites (Sibiu, Tulcea and Giurgiu). Over 400 I. ricinus and Hyalomma sp. ticks were collected and analyzed by Real-Time PCR methods (included in the new TicKitqPCR detection concept) that give us results on Borrelia burgdorferi, Francisella tularensis, TBEv and CCHFv presence in the vectors.

Total RNA and DNA were and analized by in house real-time PCR reagents (included in the new TicKitqPCR detection concept) and 2 commercial kits for the BFTC detection in the I. ricinus and Hyalomma sp. pools. All reverse-transcriptions were made using random hexamers.

Specific DNAs from B. burgdorferi sl. were detected (Fla B gene target) in 20% of I. ricinus ticks and specific DNAs for F. tularensis and/or Francisella-like endosymbionts were detected (IS Ftu2 genomic isertion-like element) in 2% of the same vector species.

Specific RNAs from TBEv were detected (3’ UTR-genomic region) in < 1% of I. ricinus pools. No specific CCHFv RNAs were detected (S–genomic region) among the Hyalomma sp. pools.

The results strengthen the concern that already exists in Romania, for the enhancement the surveillance and the control measures for the tick populations but also for the means of active information of the human population about the danger of the diseases transmitted by ticks in some risk areas.

Project funded by the MEN-UEFISCDI PN II ,,Partnerships in priority areas" program, National Research Grant No. 295/2014"

NERVE AGENTS SIMULANTS ISOPROPYL P-NITROPENYL METHILPHOSPONATE AND ETYL P-NITROPHENYL METHILPHOSPONATE AND THEIRS APLICATION AS ACHETYLCOLINESTERASE INHIBITORS

Cristina Anca Secară, Bogdan Pătrinichi, Mihaela Ionescu, Lavinia Hinescu, Mihail-Silviu Tudosie

Background: Armies of NATO member countries are interested in the synthesis and improvment of new antidotes against chemical warfare agents.

The inherent toxicity and limited laboratory supply of CWAs has led to the development and study of safer compounds that simulate the chemistry and the reactivity of CWAs.

Objectives: Reducing the risk of exposure to chemical nerve staff who test experimental therapeutic efficacy using their simulants suitable laboratory work;

Material and method: Two nonvolatile compounds were GC-MS identified as CWA simulants, 90% purity: 4-nitro-phenyl ethyl methylphosphonate (NEMP, VX simulant), and 4-nitrophenyl isopropyl methylphosphonate (NIMP, sarin simulant). In vivo study of these compounds was performed in order to determine LD50 values, cholinesterase inhibition degree, and oxime assisted protective ratio.

Experimental data statistical analysis was perfotmed by using Student's T test.

Results: NIMP: DL50 0.45 ± 0,002 mg/kg i.p; AChE inhibition in the range 53 to 95%, antidote protective ratio: 2.5; NEMP: DL 50 0.51 ± 0,003 mg/kg i.p. AChE inhibition in the range 56 to 88%;

Conclusions: Comparative analysis of LD50 values for NIMP, NEMP and CWA correspondents showed lower intrinsic toxicity of the compounds synthesized. Inhibiting activity is sufficient to mimic exposure to CWa, being present all the clinical signs typical of poisoning.

Thus it can be concluded that the two compounds studied show similar pharmacodynamic effects and references due to lower intrinsic toxicity may be suitable as a surrogate for studies in the laboratory.

THE IMPACT OF CYP2C19 POLYMORPHISMS, CLINICAL AND LABORATORY VARIABLES ON PLATELET RESPONSE TO ANTIPLATELET

Alina Mărginean, Claudia Bănescu, Valeriu Moldovan, Alina Scridon, Mihai Mărginean, Rodica Bălaşa, Smaranda Maier, Mariana Ţăruşi, Minodora Dobreanu

Introduction: Antiplatelet drugs are widely used in patients with acute coronary syndromes or stroke. Despite adequate antiplatelet therapy, some patients develop acute ischemic events. This is partly attributed to the fact that they have poor inhibition of platelet reactivity despite treatment.

This study aimed to assess the impact of clinical and laboratory variables on platelet response to clopidogrel and/or aspirin, evaluated using impedance aggregometry in a Romanian population.

Methods: The study included 189 patients with acute coronary syndromes and non-cardiogenic ischemic stroke. Platelet aggregation was evaluated by impedance aggregometry. CYP2C19 loss-of-function polymorphisms were detected using the Polymerase Chain Reaction - Restriction Fragment Length Polymorphism technique. Various clinical and laboratory data were also recorded.

Results: In our data set, 81% of the patients were responders and 19% non-responders to antiplatelet therapy. The distribution of CYP2C19 polymorphisms was as follows: 61.1% of patients were CYP2C19 wild-type homozygotes, 27.7% CYP2C19*2 heterozygotes, 1.1% CYP2C19*3 heterozygotes and 10% of patients CYP2C19*2 homozygotes. The highest level of association with clopidogrel response status was found for CYP2C19 polymorphisms, concomitant aspirin treatment, leukocyte and platelet count, history of myocardial infarction and arterial hypertension. Aspirin response status was associated with coadministration of beta-adrenergic blockers and with history of myocardial infarction.

Conclusion: The prevalence of antiplatelet resistance in our population was in line with that reported for Western populations. Clopidogrel response was significantly influenced by the presence of CYP2C19 polymorphisms. Interestingly, the concomitant use of aspirin had a significant impact on platelet response to clopidogrel, indicating a synergic interaction between these drugs.

IS ONE-SIZE-FITS-ALL STRATEGY ADEQUATE FOR PLATELET STORAGE?

Eker Ibrahim, Yilmaz Soner, Cetinkaya Riza Aytac, Unlu Aytekin, Pekel Aysel, Acikel Cengizhan, Sebahattin Yilmaz, Gursel Orhan, Avci Ismail Yasar

BACKGROUND: Preservation of platelets in room temperature increases their recovery and survival in vivo following transfusion, thus their use decreases the frequency of prophylactic platelet transfusions and the risk of alloimmunization in patients with hypoproliferative thrombocytopenia.

However, recent data also shows that the viability and hemostatic functions of platelets preserved at 4°C are higher than the platelets preserved at 22°C. We investigated and compared the viability and hemostatic functions of platelets stored at both 4°C and 22°C.

MATERIALS AND METHODS: Fresh apheresis-derivated (ADPs) and random platelet suspensions (RPSs) (n = 10 per group) were assigned to storage at 4°C or 22°C in agitators for 48 hours. Viability levels and hemostatic functions of all groups were assessed using flow cytometry and thrombin generation tests, respectively.

RESULTS: The mean platelet counts of ADPs and RPSs were 1195.2 ± 153.5 x 103 /μL and 1008 ± 304.9 x 103 /μL, respectively.

There were no statistically significant differences between the viability of platelets in ADPs stored either at 4 °C or 22 °C for 48 hours. Likewise, viability of platelets in RPSs stored either at 4 °C or 22 °C for 48 hours were not statistically significantly different. Although the ADPs and RPSs stored at 4 °C for 48 hours generated higher total thrombin levels, the differences were not statistically significant when compared to suspensions stored at 22 °C.

On the other hand, ADPs and RPSs at 4 °C for 48 hours groups generated statistically significantly higher peak thrombin levels. Moreover, 4°C/48 hours group ADPs' time to thrombin generation and time to peak thrombin generation were significantly shorter. (Table 1, 2)

CONCLUSION: The viability of platelets stored at 4°C was not different but their hemostatic activity was higher than the platelets at room temperature.

Given the superior safety profile of refrigerated platelets for bacterial contamination, creating storage conditions for specific transfusion targets may be a prudent approach, especially for improving the outcome of bleeding trauma casualties of military conflicts.

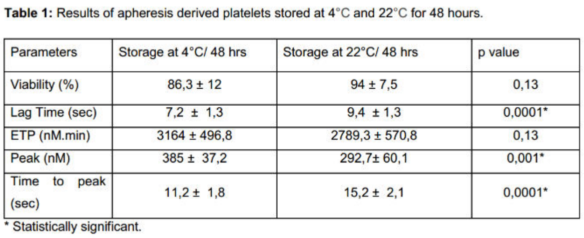

Table 1: Results of apheresis derived platelets stored at 4°C and 22°C for 48 hours.

Parameters	Storage at 4°C/ 48 hrs	Storage at 22°C/ 48 hrs	p value
Viability (%)	86,3 ± 12	94 ± 7,5	0,13
Lag Time (sec)	7,2 ± 1,3	9,4 ± 1,3	0,0001*
ETP (nM.min)	3164 ± 496,8	2789,3 ± 570,8	0,13
Peak (nM)	385 ± 37,2	292,7± 60,1	0,001*
Time to peak (sec)	11,2 ± 1,8	15,2 ± 2,1	0,0001*

* Statistically significant.

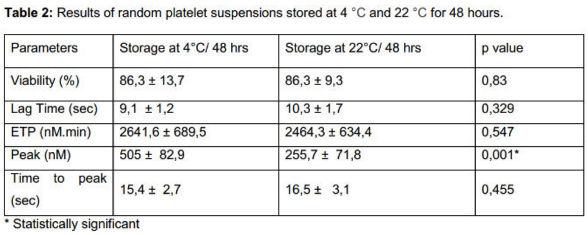

Table 2: Results of random platelet suspensions stored at 4 °C and 22 °C for 48 hours.

Parameters	Storage at 4°C/ 48 hrs	Storage at 22°C/ 48 hrs	p value
Viability (%)	86,3 ± 13,7	86,3 ± 9,3	0,83
Lag Time (sec)	9,1 ± 1,2	10,3 ± 1,7	0,329
ETP (nM.min)	2641,6 ± 689,5	2464,3 ± 634,4	0,547
Peak (nM)	505 ± 82,9	255,7 ± 71,8	0,001*
Time to peak (sec)	15,4 ± 2,7	16,5 ± 3,1	0,455

* Statistically significant

THE PREVALENCE OF PARASITES IN DONKEYS FROM DIFFERENT REGIONS OF GREECE

Starras Alexandros, Dimanopoulou Anastasia

Aim: The purpose of present study was to investigate the prevalence of donkey parasites in Greece.

Materials- Methods: The total number of the donkeys examined was 143. From every donkey included in the survey there were collected samples of faeces directly from the rectum and blood samples from the jugular vein. Furthermore, every animal was inspected in detail so as to find ectoparasites such as: a) lice especially in the body regions of neck, crest, withers, shoulders and back, b) ticks in all over the body, c) mange mites with the use of scraping test from parts of the skin appearing relative symptoms and d) fleas by using a specific comb to examine the presence of the parasites or their faeces.

Results: The endoparasites found in donkeys' faecal samples were strongyles (71.32%), Anoplocephala spp. (29.37%), Parascaris equorum (18.18%), Strongyloides westeri (6.29%), stomach spirurids (Habronema spp, Draschia spp.) (3.49%), Oxyuris equi (1.39%) and Dictiocaulus arnfieldi (1.39%). On the other hand, the only ectoparasites found in this survey were the lice species Damalinia equi (14.68%).

Conclusions: Donkeys, as reservoir host for equine parasites, can affect the health of other equids still used in many native armies. Moreover, nowadays donkeys are used for milk production. Hence, knowledge about their health status is also essential for public health.

SHOULD SANITARY DOOR OPENER BE USED TO PREVENT BACTERIA TRANSMISSION VIA THE HANDS OF KITCHEN WORKERS?

Celik Cagatay, Oz Baris, Topcu A.

BACKGROUND: WHO emphasizes the importance of preventing healthcare-associated infection (HCAI) by giving priority to the promotion of hand hygiene best practices in health care. poor hand hygiene has effects on Food Hygiene and Safety which may cause deadly foodborne illnesses all over the world. We aimed to determine bacterial flora on door handles as one of the main points of cross contamination in facility, and assess efficacy of "Sanitary Door Opener" as a troubleshooter.

METHODS: The study was carried out different 80 barracks in 3 months. Merck Swab Test Kit - Envirocheck® Contact C (Merck 1.02136) slides were used to obtain surface samples and bacteria counts. Samples were collected spontaneously from restrooms' door handles in facility used by dining facility and kitchen workers.

RESULTS: Eighty samples were collected and evaluated for Total Aerobic Bacterial Count and Coliform Bacteria Count. The results were obtained from plate count agar by counting colonies to obtain total aerobic bacterial count and from Chromocult coliform agar by counting red colonies to count coliforms. Overall, 81.25% and 81.25% of samples were positive for total aerobic bacteria and coliform bacteria, respectively.

CONCLUSION: Coliform microorganisms were present at significant levels, 81.25%, on restroom door handles in dining facilities and kitchens. At the handling level of food processing in kitchens, Coliform microorganisms are indicator bugs as in the other levels. Therefore, should take preventive measures to get rid of possibility of contamination from hand to hand by using restroom door handles. This study recommends use of ''Sanitary Door Opener'' more than the other options such as automatic folding door in terms of the cost effectiveness.

PERIPHERAL NERVE INJURY AND NEURON REGENERATION

Andreea Benga, Fatih Zor, Ahmet Korkmaz, Bogdan Marinescu

Peripheral nerve injuries can be most disabling, resulting in loss of sensitivity, motor function and autonomic control in the involved anatomical segment. Although capable of regeneration there is still no optimal solution for their reconstruction. Nerve regeneration has several vulnerable points that could be addressed to improve outcome: (1) neuron survival after trauma, (2) gap crossing and orientation of neurites, (3) neuroma formation, (4) target-organ trophicity.

Inflammation is an important sequence in nerve regeneration. Cytokines released by macrophages and fibroblasts have mitotic effect on Schwann cells. Fibroblasts are present in epineurium, perineurium and endoneurium. If they proliferate extensively, scar formation occurs that impedes nerve regeneration. Scar tissue contains repulsive proteoglycans (such as chondroitin sulfate) and semaphorins that inhibit neurites' elongation.

Nerve repair still faces two immense challenges: fascicules orientation that could be addressed by improving the surgical technique and the time race against fibrosis and end-organ atrophy amenable to pharmacological therapy.

The aim of this study is to review the literature for the most frequent chemicals used in experimental studies to address neuron survival, reduce scar formation and improve overall nerve regeneration.

SEASONAL INFLUENZA VACCINATION: FACILITATING OR INHIBITING FACTORS

Mellidis Christos, Sfikas Georgios, Katsimardou Alexandra, Iosifidis Georgios, Iosifidou Eleni, Koumaras Charalambos, Doumaki Eleni, Psomas Evangelos, Tapazidis Vasileios

Purpose: We investigated the percentage of influenza vaccinated patients among those who where clinically examined in the ER by an internal medicine specialist. Reasons for this percentage were sought.

Materials and methods: A total of 6528 patients with influenza symptoms visited the ER of 424 General Military Hospital during the influenza outbreak periods (November till March) from 2008 till 2014. During history taking, patients were given a relative questionnaire.

Results: High risk patients were found to be vaccinated 39% of the time, whereas 45% of the total patients examined were vaccinated. Reported reasons for the vaccination were: desire to avoid illness (61%), family doctor advice (35%) and desire to avoid illness spreading in family environment (4%). Reasons against the vaccination were: personal belief that one does not belong to a high risk group (37%), lack of family doctor guidance (48%), family doctor omitting vaccination (12%), vaccines shortage in the pharmacies (3%).

Conclusions: Total influenza vaccination coverage rate is low. Consulting high risk groups and general population about influenza and vaccination mainly via family doctors will aid in: increase of coverage rates among high risk groups, avoidance of vaccine shortage in the market.

OP session 1 – Students session

EFFECTS OF LPS AND IFN-γ COMBINATION ON MATURATION AND FUNCTION OF HUMAN MONOCYTE DERIVED DENDRITIC CELLS

Danilovic Milos, Isailovic Jelena, Stevanovic Jovana, Tomic Sergej, Mihajlovic Dusan, Colic Miodrag

OBJECTIVE: Dendritic cells (DCs) are potent antigen-presenting cells, which are increasingly being investigated in therapy of malignance. Their maturation is mostly induced by standard cocktail containing tumor necrosis factor-α, interleukin (IL)-1β, IL-6 and prostaglandin E2. Previous findings suggested that interferon (IFN)-γ stimulates the synthesis of IL-12, which mediate a strong anti-tumorous immune response via T-helper (Th1) cells. Additionally, lipopolysaccharide (LPS) is a known DC maturation agent acting via Toll-like receptor (TLR)-4. Therefore, we compared the effects of LPS/IFN-γ combination and standard cocktail on maturation, allostimulatory and Th polarization capability of human

monocyte-derived DCs.

MATERIAL & METHODS: DCs were generated by cultivating monocytes with granulocyte macrophage colony-stimulating factor and IL-4 for 6 days. Immature DCs were then stimulated with the cocktail or with LPS/IFN-γ combination. After 24h, phenotypic analysis and DCs functions were investigated.

RESULTS: The cocktail induced a higher expression of HLA-DR, CD54 and CD83, but a lower expression of CD40 by DCs. LPS/IFN-γ-stimulated DCs produced more IL-12, but less IL-23. In addition, the co-culture supernatants of LPS/IFN-γ-matured DCs and allogeneic CD4+T cells contained higher concentrations of IFN-γ and IL-17, compared to the co-cultures with the cocktail-treated DCs. In contrast, cocktail-matured DCs induced a stronger allogeneic CD4+T cell proliferation.

CONSLUSION: Although the maturation protocol with LPS/IFN-γ exhibits weaker phenotypic maturation potency for DCs, it induced much stronger Th1 and Th17 immune responses than the protocol with standard cocktail.

IMPACT AND INTERVENTIONS OF MUSIC ON HEALTH

Charitidis Nektarios, PagkratI Vasiliki

Purpose: Music is a universal feature of all human cultures and appreciated as such. The primary and specific aim of this study is to record the therapeutic effect of music as a healing tool for hospitalized patients and its' effect on a wide range of diseases. The secondary aim, is to investigate and document the positive contribution of music in all branches of general public health.

Material and Methods: Collected data came from a review of the international bibliography (research studies and articles found on Pub Med).

Results: From the comparison and screening of the collected data, most studies confirm and document the beneficial effects of music on separate and general fields of health. Regarding hospitalized patients, music helps and enhances the healing and recovery process of many diseases and unbalanced health conditions; it also generates a serene, stress-free and patient-friendly hospital environment for patients, within which, healthcare professionals can perform "lege artis”. In terms of general public health, research proves that music is a beneficial factor that improves productivity and stamina and also results in physical, social and mental well-being, by reducing stress, depression, grief, loss, sorrow and similar emotional states.

Conclusion: Music is a low-cost, universal and multicultural therapeutic tool that can be used as an alternative therapy in many cases, a fact well supported by search-based findings, but not yet accepted by the majority of medical community. Therefore, healthcare professionals should educated further in order to implement and evolve music in patient care, because of its effectiveness.

MULTIPLE CASUALTIES INCIDENTS – THE IMPORTANCE OF EARLY SPECIFIC TRAINING OF MILITARY MEDICAL PERSONNEL

T.C. Mures, Maria M. Ancuta, R. A. Zamfir, B. S. Zamfir

Introduction: MCI has always been a challenge even for well-developed health systems. The geo-climatic and socio-economic current conditions clearly predispose us to increased incidence and magnitude of such events. Moreover, the current trend of the evolution of armed conflict to asymmetric and unconventional confrontations causes increasingly frequent incidents which involves civilians in armed military conflicts, representing an additional risk factor. In this context, the contribution of military medicine at the management of civil MCI can be particularly valuable both in human terms and in terms of capabilities.

Material: The sudden and unexpected onset, the major destructive effects, unpredictable developments and major impact both physical and psychological on the intervention personnel are the main features of the MCI. These characteristics superimposed over a high level of current activity destabilize the health systems. To ensure an adequate emergency response, procedures are conducted after specific and complex operation plans that differ substantially from those used in the current work routine. The knowledge and application of these procedures accurately by the staff involved is essential to ensure actional interoperability between the structures participating in the intervention.

Conclusion: Acquiring, maintaining and improving knowledge and skills needed to perform, in conditions of extreme physical and mental stress, the complex activities provided in emergency response procedures require completion of a gradual and continuous program of specific training. Ideally, this program will begin as early as possible in the medical career.

CONSIDERATIONS REGARDING TACTICAL

EVACUATION CARE

Iulia-Madalina Staicu

Introduction: Lessons learned from more than a decade of war in Afghanistan showed that many potentially preventable deaths have occurred until casualties reached a medical treatment facility (MTF).

Materials and methods: Research work on the available medical literature by searching databases (Medline, Wiley, Science Direct), selected articles published since 2012 to 2015. Search terms included: medical treatment facility, tactical evacuation care, stress, aeromedical assets.

Results: Our paper deals with one important factor which could reduce these deaths – the third phase of tactical combat casualty care – tactical evacuation care (TEC). After a brief history regarding medical evacuation, we describe the concept of TEC with stress on some important factors which influence the mortality during this phase of care when are used aeromedical assets.

Conclusions: Almost 90% of all combat deaths occur before the casualty reaches a Medical Treatment Facility (MTF). One of the most important factors to reduce the mortality in tactical evacuation phase of care is to have well equipped evacuation assets, manned with well-prepared medical personnel.

RELATIONSHIP OF SOLITARY GLIOBLASTOMAS TO THE FUNCTIONAL REGIONS OF THE BRAIN

Bulatovic Jelena, Ljubenovic Nenad, Hadzija Helena, Despotović Dragana, Peric Predrag

OBJECTIVE: Maximal safe resection of glioblastoma (GB) depends on its size and anatomical localization (AL). Functional localization (FL) limits or disables tumor resectability.

AIM: Determination of AL and size of GB, and their relationship to the functional brain regions (FBRs).

MATERIAL & METHODS: We analyzed pre-operative magnetic resonance imaging of the brain in DICOM format of 19 patients with primary, solitary GBs of the brain. The size of GB was determined as maximal clinical diameter (MCD) of tumor hyperintensity signal on T2W/FLAIR sequence, and as maximal morphological diameter (MMD) of tumor contrast enhancement on T1W+C sequence. FL was defined as FBRs according to Sawaya and co-workers.

RESULTS: In analyzed patients, GB was frequently localized in temporal lobe and eloquent brain regions (52.6% and 42.1% respectively). In females, GB was significantly more frequent in eloquent regions (p = 0.039). Independently to the tumor FL, significant correlation between MMD and MCD (p = 0.022) was found, as well as highly significant difference between them.

DEVELOPMENT OF A POLICY TO INCREASE DETECTION RATES OF RARE DISEASES

M. Zahit Sarikaya, Halili Sik, Ferdi Yildirim, Mahir R. Turan, Kaan E. Bebek, Enes B. Biskiner, Huseyin Dulger, F. Cengizhan Fettahoglu, Mecit Bahar, Mustafa Gulec

Introduction: The term “Orphan Diseases” refers to extremely rare medical conditions, rare being 1:2000 in the population according to the European definition and affecting less than 200.000 people worldwide according to the American definition. There are 6 to 8 thousand rare diseases on Earth. Countries use different strategies and policies to treat or cure these conditions. First in 1983 in America, then in 1999 in Europe, different political approaches have been adopted. Rare diseases constitute a global problem; thus, they require creation of shared databases and extensive studies. We don’t have an extensive study about rare diseases in our country yet.

Method: First, the website “orpha.net” was utilized to collect information about the 100 most common rare diseases. Then, our hospital’s data center was searched for records of the ICD-10 codes of these diseases between January 2011 - February 2015.

Results: We found 11.238 diagnoses of rare diseases among these admissions. We analyzed some clinical qualifications of these patients in SPSS.

Discussion: We aimed to acquire epidemiological data about these diseases, since there was not a related research in our country. If this research can be applied in other hospitals in the country, nationwide epidemiological results can be achieved, and a shared database for further studies will be possible.

PUBLIC AWARENESS IN CHRONIC DISEASES

Eda Demirtas, Bekir Dogan, M. Emin Karayigit, Yavuz S. Yalcin, Faruk Colak, Sevde B. Okuducu, Nurperi H. Acar, Aydın Bagdat, Okkes Yigit, Muhsin F. Yildirim, Abdulgani Bakar, Sumeyra Altun, Merve Arslan, Ugur Isik, Unal

Zengin, Ilker Yilmaz

Objective: By definition, a chronic disease is one lasting 3 months or more. Chronic diseases constitute 63% of all death causes. The most frequent causes of chronic disease are: 1. increased blood pressure (13%), 2. tobacco products (9%), 3. increased blood glucose (6%), 4. insufficient physical activity (6%), 5. overweight and obesity. We aimed to increase the awareness of people about hypertension, cigarette, diabetes and obesity risk factors.

Material- Method: Four different risk evaluation forms were developed to assess four major health problems of cigarette, diabetes, hypertension and obesity. Then, informative posters were prepared and communication booths were established in our hospital. Blood sugar levels, blood pressure, waist circumference, height and weight were recorded for every visitor. In light of the measurements, we filled the risk evaluation forms for each patient. We recommended patients whose conditions were found to be risky in terms of four health problems to visit related outpatient clinics. We also noted the contact information of the patients for further follow-up studies.

Results: In light of both our observations during the activity and results obtained from the risk evaluation forms, consciousness and awareness were significantly insufficient among the patients. Overall, our data suggest patients do not tend to quit cigarette unless they had had heart attack or malignancy. Also, patients do not develop healthy nutritional habits unless they are diagnosed with diabetes. There were some patients whose blood pressures were measured for the first time in their lives.

Conclusion: Public awareness in chronic diseases is lower than expected. Further studies aiming to inform the public about complications of chronic diseases are urgently needed.

EVALUATION OF ENVIRONMENTAL HEALTH AND CONDITIONS OF STUDENT LIVING AREAS IN A FACULTY OF MEDICINE

Zeynep Eslem Gokcek, Furkan Taha Birinci, Burak Cengeloglu, Fethi Dilber, Hulya Kapucu, Talha Kivanc, Muhammed Muaz Kusen, Ali Uygun, Burhan Poyraz, Yavuz Selim Yalcin, Recai Ogur

Objective: Environmental health is focused on the natural and built environments for the benefit of human health. In this study, we focused on 5 major factors that we considered are most influential on our campus life: microbiological air quality, electromagnetic radiation (EMR), noise, swab culture and illumination.

Methods: Microbiological analyses, EMR, noise measurements, swab culture and illumination measurements were carried out in the following places with respective specific devices: dormitories, study halls, bathrooms, public toilets, hallways and cafeterias.

Results: After the statistical evaluation of microbiological measurements, statistically significant differences were found between room population and bacterial pollution (p=0.020). For EMR, a statistically significant difference was found between room population and study rooms' measurement at 20.00 PM. Also, statistically significant differences were found between room population and EMR measurements at 01.00 AM (p=0.028, p=0.016; respectively). Also, there were statistically significant differences between noise measurements at count time and 01.00 AM (p<0.001) A significant statistical difference was found between gender and colonization in fridges according to colony counts of swab cultures (p=0.011). There were statistically significant differences between room types and illumination in all conditions of lighting (p<0.01).

Conclusion: Conditions and problems of our faculty were investigated using 5 major parameters.

OP session 1 – Nurses session

TURKISH NURSING STUDENTS' KNOWLEDGE OF AND ATTITUDE TOWARD HIV/AIDS AND THEIR

WILLINGNESS FOR CARE RELATED TO PATIENTS WITH HIV/AIDS

Kok Gulsah, Guvenc Gulten, Kaplan Zeliha

OBJECTIVE: Studies have shown that healthcare providers have negative attitudes toward and fear of people living with HIV/AIDS because of lack of knowledge and the stigma attached to the disease, and fear of the possibility of becoming infected, and hesitate to provide care to HIV/AIDS. The aim of this study was to determine Turkish nursing students' HIV/AIDS knowledge, attitudes, and willingness care related to patients with HIV/AIDS.

MATERIAL AND METHOD: Cross-sectional design was used in this descriptive study. Participants were nursing students from a School of Nursing in Ankara, Turkey during 2013–2014 academic years. A total of 325 nursing students volunteered to attend this study and all of them were female. Data collection form, HIV/AIDS Knowledge Questionnaire, and AIDS Attitude Scale were used for data collection. The data were analyzed using SPSS for Windows version 15.0.

RESULTS: The mean age of participants was 20.56±1.05. The mean score for AIDS attitude scale was 49.50±10.57. The mean subscale scores for contagion, negative emotions, and professional resistance were 20.88±4.24; 12.99±3.64; 15.61±6.10 respectively. The mean knowledge score was 13.76 ±2.88, and mean score for willingness to care was 4.30±1.76. There were significant differences in median scores of knowledge, AIDS attitude scale and subscales among nursing students.

CONCLUSION: The current results reveal that nursing students have moderate level of knowledge about HIV/AIDS and that their attitudes need to be improved. Inadequate knowledge, negative attitudes towards patients with HIV/AIDS, and consequent fear may result in less than optimal care for patients with HIV/AIDS.

FLIGHT NURSE SCHOOL IN THE HELLENIC AIRFORCE

Katsika Alexandra

Purpose: To inform about the operation of Flight Nurse School in the Hellenic Airforce, under the Aerospace Medicine Centre, in order to provide specialized nursing personnel for air evacuated patients, during peace and war time, as well as to advance the quality of nursing care and ensure their ability to respond in every emergency condition involving medevac. The structure and performance of school conducted in accordance to US/Canada FN Schools, corresponded to the abilities and needs of our country.

Material: Data were collected from Flight Nurse School records and the Operation's Regulation of Aerospace Medicine Centre.

Results: Since 1988 a total number of 284 Officer Nurses and 27 petty officers of the HAF, 11 Officer Nurses of the HN, 20 Officer Nurses of the HA and 24 civilian paramedics of the Hellenic National Emergency Aid Centre, have graduated from school Education at school includes:

- Theoretical part about stresses of flight, mission planning, emergency situations in flight, combat casualty care and triage.
- Practical part includes low pressure chamber, practice in sea survival and real flights.

Conclusions: FN School offers a unique and broad field to professional nursing, with an opportunity to serve patients, community and Armed Forces as a basic part of Aerospace Medicine. Greece is one of NATO members that can afford specialized Flight Nurses during Medevac, according to NATO STANAGS, while we are considering the possibility of training others' countries officers, as soon as specific difficulties will be overcome.

NURSE'S ROLE IN LASER ASSISTED REFRACTIVE SURGERY

Mihai Florentina, Grigore–Ghita Ana–Maria

Introduction: Refractive surgery is one of the most rapidly evolving fields in ophthalmology. It is used to correct refractive errors such as myopia, hyperopia, astigmatism and presbyopia.

This field of surgery evolved rapidly with the development of excimer laser assisted procedures, the most commonly used being LASIK.

Systematic review methodology: This study is a review on laser assisted refractive surgery, emphasizing the role of the nurse in patient's care.

Results: A critical part of this procedure is the perioperative care of the patient and, as such, the nurse. Nursing involves deep human interpersonal relationships between nurses and patients and it is an essential part of the patient's care.

Conclusions: The nurse is a critical part of the perioperative care of the patient.

If a patient decides, after careful consideration, to do this procedure, he must meet some criteria, carefully selected to limit the postoperative complications.

Even if patient’s satisfaction after this type of procedure is usually high, there are various complications that may occur, depending on the type of procedure used.

BREAST CANCER IN YOUNG WOMEN

Margareta Popa

Living with breast cancer can be a difficult proposition. In women who have had a mastectomy, altered body image can be a challenge. Young women are especially vulnerable because of their age.

Breast cancer at a young age though the age definition for young is very variable, has been reported to pursue a more aggressive clinical course and to be associated with a more unfavorable prognosis compared with the disease in older patients.

About 5-10% of all breast cancer is thought to be hereditary. When a women is diagnosed with breast cancer at a young age (i.e. under 40 years), we are concerned that she might have developed her cancer due to an inherited predisposition.

Young women who learn they carry a mutation in a gene conferring a high risk of breast cancer must make a plan for managing their cancer risk over time. Today, there are several option for women, but unfortunately, all involve significant trade-offs:

- Increased surveillance
- Prophylactic surgery
- Chemoprevention

Diagnosis of breast cancer presents the young woman with a whole range of challenges. In addition to the physical and existential threats, there are the prospects of disfiguring surgery and complex adjuvant treatment with its unpleasant side effects. She is also at risk of psychological, familial, occupational, financial and social problems.

Breast cancer at young age often occurs before reproductive plans have been completed and reproductive issues, including fertility, pregnancy, contraception and menopause, are therefore of great importance for this growing number of young breast cancer survivors.

Expectations of young women concerning psychological intervention are slightly different from the needs of the older patients. However, family support is the most important for them, there is strong expectation of psychological support from clinical professional. Availability of such help should be maintained much more intensely.

PRESENT AND FUTURE OF HEARING AIDS

Ileana Mariana Mateș

The hearing aids (Receiver-In-The-Ear, Behind-The-Ear, In-The-Ear, Canal Hearing Aids, Cochlear Implants, Bone Anchored Systems) have performed a vital process for people suffering of hearing problems for almost two centuries, but fortunately they have rapidly evolved after decovering the microprocessor in 1970s.

If we look to the future, scientists are working for developing new and exciting solutions in hearing aid design. Scientists from all over the world are developing future devices including

- laser-signalled hearing aids with a larger frequency range,
- permanent in-ear hearing aids which never have to be removed because they use induction charging rather than batteries.
- regeneration of damaged parts of the inner ear using stem cells

In our days, the major players in the hearing aids market are Cochlear Limited (Australia), GN Store Nord A/S (Denmark), MED-EL (Austria), SeboTek Hearing Systems, LLC (U.S.), Sivantos Pte. Ltd. (Singapore), Sonova (Switzerland), Starkey Hearing Technologies, Inc. (U.S.), Widex (Denmark), William Demant Holding A/S (Denmark), and Zounds Hearing, Inc. (U.S.).

The hearing aid devices segment is expected to account for the largest share of the global hearing aids products market in 2016, and the global hearing aids market is expected to reach USD 8,373.9 Million by 2020 from USD 6,183.3 Million in 2016.

OP session 2 – Aerospatial and diving medicine

THE INFORMATION SEEKING BEHAVIOR OF GREEK AIR FORCE MILITARY DOCTORS

Evangelos Persakis, Petros Kostagiolas, Eleni Lazaridou, Georgios Toloumis

Aim: This paper aims to study the information seeking behavior of Greek Air Force military doctors and thereafter inference on the role of information needs satisfaction at operational level. We call this interaction "INFORATION" combining the words "information and operation."

Material – Method: The research was based on empirical evidence from a survey informed by Wilson's macro model of information-seeking behavior. The data includes 101 military doctors of 251 Air Force General Hospital, in Athens, Greece.

Results: The method was successful in identifying operational information needs, information resources employed and the obstacles military doctors face when seeking information. The most important information needs of the physicians were related to diagnosis, treatment, research, updating of knowledge and instruction-educational issues. Online resources such as scientific databases, search engines and scientific journals were the most important information resources, while the major obstacle encountered by the doctors was the lack of access to online scientific databases from the workplace. Significant associations were identified and discussed.

Conclusions: The information seeking behavior and needs of Greek Air Force military doctors should be, at operational level, addressed as an integral part of the development of information systems and information services especially for that category of doctors.

NIGHT VISION DEVICES USE IN HELICOPTER AIRCREW - HUMAN FACTOR ASPECTS

Stefanescu Cristina, Stefanescu Cristian-Dragos

Introduction: Night Vision Devices (NVD) have become an essential component of modern military aviation. It offers enhanced performance qualities compared to unaided night vision, more useful during the execution of missions at night, but at the same time their use is tributary to some limitations that should be known and accepted (both technical, and human factor related).

Material and methods: We used an anonymous questionnaire (transversal observational study) applied to helicopter pilots using different types of NVD (military flight), totaling 46 respondents. Thus we could analyzed various aspects of using these devices in terms of human factors (assessment of their benefit in terms of morphoscopic acuity for different distances, stereoacuity and depth perception, visual field extend ,contrast sensitivity quality, benefits in different phases of flight and in various flight conditions), and problems faced by the user: the fatigue phenomenon (description, cause, duration), spatial disorientation and "black hole illusion", if the simulator can reproduce the situations faced by the pilot in real flight, and the importance of a basic professional course as well as continuous training.

Conclusions: The aria of concerns about flight safety must include the mandatory use of NVD. Most important for quality skills are proper and continuous training.

ROMANIAN MILITARY MEDICINE CONTRIBUTION IN AIRMEDEVAC CAPACITY BUILDING IN BOSNIA AND HERZEGOVINA

Pintilie Daniel-Iacob, Tudose Dragoş-Cristian, Nică Daniel-Florin

As of 2008, Bosnia and Herzegovina applied for NATO membership as Partnership for Peace member. Therefore, in order to achieve NATO standards, one of the objectives was to develop a structure to provide AirMEDEVAC capabilities for Bosnian and NATO forces as well. The project started in 2010 with Romanian Air Force Mobile Training Team as part of ALTHEA mission in BiH, and continued from 2012 with Romanian Air Force AirMEDEVAC Advisory Team. The Romanian Air Force developed an Air Medevac structure, evaluated by NATO through STARTASSES process.

Materials & methods: This paper provides a review of the most important aspects of the capacity building regarding AirMEDEVAC capability: available resources, project development, challenges, and further development. The project is to be evaluated by NATO during 2017.

Results: The long term mission and the tremendous logistic, medical and operational challenges resulted in building an updated functional structure in BiH Armed Forces dedicated to Air Force missions in general and medical evacuation in particular.

Conclusion: The recent experience of Romanian Air Force in developing an AirMEDEVAC structure is of help for surpassing the tremendous challenges encountered by BiH Armed Forces in the process of building their own AirMEDEVAC capacity.

DECOMPRESSION RISK AND INTENSIVE PHYSICAL EFFORT AFTER DIVING

Shopov Nikola, Vazharov Ivaylo

Introduction: The effect of post-dive exercise on bubble formation remains controversial. There are studies, including ours, showing that moderate physical activity before diving can reduce the risk of decompression. One 2006 study suggests that heavy post-dive exercise might be beneficial, although it was done on fit military. After the number of cases of decompression sickness (DCS) in divers involved in catching shells does not diminish, our hypothesis is that heavy exertion immediately after diving is probably inadvisable.

On the other hand the most likely factor initiating DCS is believed to be the formation of bubbles in the blood and the tissues. It is generally accepted that the incidence of DCS is lower when few or no bubbles are present in the circulation from hyperbaric exposures. Further, it is hypothesized that heavy anaerobic efforts immediately after the dive will significantly increase Doppler detected bubbles, which may be the reason for the increase in cases of DCS.

Purpose: The purpose of this study was to examine the impact of strenuous physical activity after a dive on decompression risk.

Materials and Methods: 22 non well-trained divers participate for this study (average age: 32 ± 8 years and Body Mass Index: 24 ± 4.2 kg m^{-2}). Each diver performed two type of dives (during 3 days) in a hyperbaric chamber in depth 18 m for 60 min with decompression stop on 3 m for 5 min according to the French Tables de plongee a l’air Marine Nationale (MN 90). One type dive is without performing physical effort after decompression and after the second dive was carried out intense exercise. Physical exercise consisted of two cycles of five minutes, with one minute rest, consistently performing 10 crunches, 5 push-ups and 10 squats with 20 kg weight. After each dive be performed Doppler monitoring by using a bi-directional Doppler (BIDOP ES 100-V3 – HADECO, Japan) with 2MHz transducer. Bubbles are detected in the precordial area with the usage of the Kisman-Masurel code. Monitoring was performed at 30, 60 and 90 min after surfacing and we observed for the maximum bubble grades - MBG (bubble peak). The bubble grade was subsequently used to calculate the Kisman integrated severity score (KISS). KISS was assumed to be a meaningful linearised measure of post-decompression intravascular bubble activity status that may be treated statistically.

Results: Anaerobic intensive workloads significantly increased Maximum Bubble Grades (Δ = 0.53; r = 0.718**; p < 0.01) and KISS (Δ = 6.72; r = 0.869**; p <0.01). Nobody demonstrated a decrease in venous bubble grade after dives with exercises.

Conclusion: These results suggest that post-dive strenuous exercises after a single dive significantly increased post-dive gas bubble formation in poorly trained divers and perhaps leading to increased of decompression risk.

COSMIC RADIATION AFFECT ON WOMEN WHO USE WARPLANES: A CUMULATIVE DOSE STUDY

Ozturk Mustafa

BACKGROUND During flights, pilots, flight personnel, and passengers are exposed to cosmic radiation originating from galactic rays and solar system. The term cosmic radiation is the conjunction of solar and galactic radiation that originates from the sun and other planets and stars, respectively. Cosmic radiation consists of neutrons, protons, electrons, and photons, and human skin is permeable to these particles, which can cause alterations within live cells on a molecular level. This article reviews the effects of cosmic radiation on women who use warplanes.

MATERIALS AND METHODS We calculated the cosmic radiation exposure of women who use warplanes. We implanted cosmic radiation calculators into pilots’ (F 16, CASA and helicopter) uniforms. Exposure to cosmic ionizing radiation was calculated by the Turkish Atomic Energy Authority after 1 month. All flights were calculated according to July datasets because the maximal radiation exposure effect is considered to be in the month of July.

RESULTS According to the reports of the ICRP in 2003 and 2007, doses below 10 rads (1 rad = 10 mSv) have no demonstrable influence on humans. For nonpregnant people, the cosmic radiation response dose has been established at 50 mSv per month. The allowed radiation doses are 0.5 mSv per month during pregnancy. Domestic flights do not exceed the recommended monthly limit for women.

CONCLUSION We evaluated the maximum cosmic radiation exposure effects on women using warplanes. The exposure for pilots was found to be below the risk level.

AEROMEDICAL EVACUATION OF ABDOMINAL GUN SHOT WOUNDED PATIENTS IN POSTOPERATIVE EARLY PHASE

Acar Yahya Ayhan, Uyguner Cem, Tezel Onur, Salman Necati, Dede Hakan

OBJECTIVE: There is still debate on optimal post-operative time for aeromedical evacuation of abdominal surgery patients. This study aims to evaluate the risk factors associated with aeromedical evacuation of patients with abdominal gunshot injury in early postoperative phase.

MATERIAL AND METHOD: This is a retrospective analysis of abdominal gunshot wounded patients which were transported by air ambulance system of Turkish Armed Forces. Data were collected retrospectively from the patient records between 1998 and 2015. Patients divided into two groups according to postoperative transport time; patients transported within postoperative three days (GROUP 1) and later than three days (GROUP 2). Besides demographic data, flight crew number, pre- and post-transport vital signs of the patient, airway status (spontaneous, mechanically ventilated), vasopressor and/or volume replacement therapies used in flight were recorded. SPSS 15.0 (SPSS Inc., Chicago, IL) was used for statistical analysis and $p<0.05$ considered as statistically significant.

RESULTS: A total of 217 patients were enrolled in the study. All of them were transported with a fixed wing aircraft (CN-235) air ambulance. No deaths occurred during transport. There was not any difference in age and gender between two groups ($p=0.385$ and 0.244, respectively). Mechanically ventilated patients and vasopressor use showed a higher rate in group 1 ($p=0.001$ and 0.011, respectively). There was not any difference in pre- and post-flight systolic blood pressure levels and flight crew number between two groups ($p=0.122$, 0.775,and 0.865, respectively).

CONCLUSION: Patients with abdominal gunshot injury can be transported safely by air ambulance in early postoperative phase.

THE ROLE OF MILITARY AIRCRAFTS IN TRANSPORT OF ROMANIAN CITIZENS INVOLVED IN MASS CASUALTY INCIDENTS

Leonard-Marin Lupu, Bogdan Teusdea

A mass casualty incident (MCI) is any incident in which emergency medical services resources, such as personnel and equipment, are overwhelmed by the number and severity of casualties.

A MCI can involve many and varied types of responders and agencies. Once an MCI has been declared, a definite and well coordinated flow of events will occur, using three separate phases: triage, treatment, and transportation. When a complex type of injures are present (for example severe burns or major trauma injuries), which need special medical facilities to be treated, then the situation may become critical considering the public impact of the incident.

A complex process must be implemented very quickly in order to identify domestic or foreign hospitals specialized in burn or trauma treatment, to make all the necessary arrangements, to transport the patients in a proper way and to sustain all this efforts.

The use of military medical aircrafts proved to be a valid option for long-distance evacuations. Military assets could play a great role in an MCI situation but without preplanning and scenario based exercises this missions may become difficult.

PATIENTS’ SATISFACTION LEVEL IN A GREEK MILITARY HOSPITAL

Trachanatzis Theodore

Aim: The last decades, the interest of health care professionals increasingly focuses on patients’ satisfaction level of the provided care. The cost of hospitalization coupled with general quality has been the subject of a heated debate. The main objective of this research is to estimate the patients’ satisfaction level in the 251 Air Force Hospital of Athens. Additional objectives are the investigation of the factors that define it.

Material-Methods: The study population consisted of patients just before their discharge from the hospital. 150 questionnaires (close-typed) were distributed within a six-month period (May-October 2014) in total to the orthopedic and cardiology clinics. Of these, 109 were completed correctly and used in the analysis. For the statistical evaluation, Cronbach's coefficient, and the SPSS program were used.

Results: 58.7% of the sample were men. The majority of the participants was above 61 years old (26.6%), married (47.7%), with an average monthly income of 1001-1500 euros. Overall satisfaction in terms of friendliness and courtesy among patient- therapist seemed to be in a high level (81.9% and 84% respectively for the 2 clinics). Furthermore, based on the regression analysis, the education of the patients affects mainly their perception about the quality of the services.

Conclusions: On the whole, useful conclusions have been drawn regarding the provision of care. It is a fact that the high educational level and general competence of the physicians and nurses are the key elements that reflect on the patients' high satisfaction score. Quality is undoubtedly a challenge, and also an inalienable right based on the principle of humanism, and the Hippocratic ideal!

THE PREVALENCE OF THYROID ABNORMALITIES ON ULTRASONOGRAPHY AND ASSOCIATED FACTORS PREDICTING RISK PROFILE IN AVIATORS

Okur Aktaş Gökcan, Karacaer Zehra, Karaduman Mehmet, Tirmik Uzeyir

OBJECTIVE: To evaluate the prevalence of thyroid abnormalities detected on ultrasonography and its relationship with metabolic parameters which are important to describe a risk profile among aviators.

MATERIAL AND METHOD: We retrospectively reviewed medical charts of 259 aviators who were admitted to the Military Aviation Medicine Center for the annual examination in year 2014. Thyroid ultrasonography findings, age, body mass index (BMI), presence of liver steatosis on ultrasonography, laboratory parameters (TSH, fasting blood glucose, BUN, creatinine, total cholesterol, LDL, HDL, VLDL and triglyceride, TC/HDL ratio) were obtained.

RESULTS: Mean age was 35.12±5.9 years. All subjects were male. 67 subjects (26%) had thyroid abnormalities on ultrasonography. According to BMI, 69 subjects (26%) were slightly overweight (BMI 25-30 kg/m2) and of them 19 subjects had thyroid abnormalities on ultrasound (28%). Liver steatosis was found in 67 subjects (26%) and 20 subjects with liver steatosis had thyroid abnormalities on ultrasonography at the same time (17 subjects were overweight and 3 subjects had normal BMI).

Older age, higher BMI were found closely related with the presence of thyroid nodules ($p<0.05$ for all). Presence of liver steatosis and laboratory parameters including TSH were identified as independent predictors for the existence of thyroid nodules.

CONCLUSION: This study showed a positive relationship between metabolic parameters and thyroid abnormalities in aviators. Our results support that increases in thyroid nodules is partly secondary to increase in obesity.

Metabolic and sonographic abnormalities of thyroid gland and liver might be clinical indicators for further evaluation of aviators whose clinical risk profile could be underestimated by classical risk factors and hence, annual examinations for aviators should be designed to include thyroid ultrasonography.

OP session 2 – Emergency medicine and trauma management

COLECTIVE MASS CASUALTY INCIDENT – OUR EXPERIENCE

Negoiţă DD, Teuşdea CB, Toma LM, Butoi A

On the 30th of October 2015 a fire occured in a nightclub where there were a few hundred people, causing tens of deaths and dozens of injuries. A few of them got by their own means to the ED of the University Emergency Central Military Hospital Bucharest. Several of them were brought by SMURD ambulances from 2 other Emergency Hospitals (Floreasca and Coltea) following the Emergency Red Intervention Plan. 11 patients were admitted to ICU during that night. One patient denied admission at his own risk (having minor injuries). We present the peculiarities of management of these burn patients in the ER.

ULTRASOUNDS CAN ESTIMATE CEREBRAL EDEMA IN MANY WAYS THAT CAN ALSO BE APPLIED TO PREHOSPITAL EMERGENCY CARE

Karellas Ioannis, Plakas Sotirios, Lafazanos Spiridon, Tsakalakis Christos, Liapis Georgios, Gourtzelidis Pavlos

Purpose: Traumatic Brain Injuries (TBIs) are a leading cause of morbidity and mortality in modern battlefield. Increased Intracranial Pressure (ICP) due to cerebral edema is a serious complication of TBIs. This study is investigating if Transcranial Doppler (TCD), Doppler of Internal Carotid Arteries (ICAs) and Ocular Nerve Sheath Diameter (OSND) can estimate increased ICP, very important for decision making and guidance of therapy.

Material and Methods: 24 TBI patients, presented with Glasgow Coma Score<8, were sedated, intubated, mechanically ventilated and admitted in ICU. In all patients intracranial catheters were applied for direct monitoring of ICP, Mean Arterial Pressure (MAP) was invasively monitored and ONSD was measured. When Cerebral Perfusion Pressure (CPP=MAP-ICP) decreased below 50 mmHg, in parallel to aggressive therapy, a TCD scan was held, the spectral analysis of flow in ICAs was obtained and OSND was measured. Blood flow velocities were measured in both Mean Cerebral Arteries, PI (PI=Peak systolic velocity-End diastolic velocity/Mean velocity) and CPP were calculated. The TCD spectral analysis was compared with that of ICAs.

Results: 365 TCD examinations were conducted and PI and CPP was calculated. There was a strong correlation between CPP and PI (Pearson’s Correlation Coefficient: -0.782, p<0.0001) and between ONSD and ICP (Spearmen: p<0.05). The ICAs Doppler spectral analysis resembled that of TCDs and lost its diastolic component when ICP>dBP.

Conclusion: There are many ways that ultrasounds can estimate of CPP in TBI patients. Compact devices make ultrasounds applicable to prehospital care most useful at frontline for the on site evaluation of casualties.

SEPSIS – AN UPDATE

Dogaru S, Teusdea CB, Popa Luminiţa Mariana

Sepsis is not something new. Neither is the increasing awareness toward associated morbidity, mortality and costs burden. Many organizations, including regulatory agencies and hospitals are focused on sepsis quality improvement programs.

In addition, greater understanding of underlying pathophysiologic mechanisms responsible for cellular dysfunction and the significant amount of data obtained through evidence based medicine led to constant updated definitions, biomarkers study, admission criteria and protocol based treatment (Surviving Sepsis Campaign 2008 and 2012).

Fast growing medical knowledge and increasing standardization require active concern toward the very essence of this subject. This is the reason why the Sepsis Definition Task Force recently (February 2016) updated the definitions for sepsis and septic shock of whose previous versions dated back in 1992 and 2003.

Although great progress had been made there much still to be done.

POINT-OF-CARE TESTING (POCT) DEVICES IN THE EMERGENCY DEPARTMENT – OUR EXPERIENCE

Teusdea CB, Toma LM, Dogaru S, Popa Luminiţa Mariana

Point-of-care testing (POCT), or bedside testing is defined as medical diagnostic testing at or near the point of medical care - that is, at the time and place of patient care. POCT is to bring the test conveniently and immediately to the patient, making the results quicker, which allows for immediate clinical management decisions to be made.

POCT includes: blood glucose testing, blood gas and electrolytes analysis, rapid coagulation testing, rapid cardiac and sepsis markers diagnostics, drugs of abuse screening, urine strips testing, pregnancy testing, infectious disease testing and cholesterol screening.

In this study, we made a comparison between the results obtained from blood tests on POCT instruments (blood count and biochemistry), and blood tests obtained in the Central Laboratory of the hospital to determine if these analyzers can be used routinely to the emergency room.

Our study showed little difference between the two laboratory tests but with no statistical significance. Thus, POCT type tests can be successfully used in evaluating patients in ED, representing a possibility to reduce the time to treatment and to other medical decisions.

TRAUMATIC RUPTURE OF THE DIAPHRAGM

S. N. Romedea, S. Luncă, R. Tiutiuca, B. S. Zamfir

Introduction: Diaphragmatic rupture remains a diagnostic challenge because of the lack of an accurate test demonstrating the injury. The aim of this paper was to analyze our experience with management of these injuries and to identify predictors of outcome.

Material and method: Sixty-five patients were treated for diaphragmatic rupture in “St John” Emergency Hospital Iasi and Emergency Military Hospital “Jacob Czihac” Iasi, between January 2003 and April 2012. They were 52 men (80 %) and 13 women (20 %), with a mean age of 39.34 ±6.35years. Blunt trauma accounted for 16 injuries (24.61%) and penetrating trauma for the rest of 49 injuries (75.38%).

Results: The preoperative diagnostic was established for 18 patients, 7 blunt and 11 penetrating. Thirty-one patients (47.69%) presented with hemorrhagic shock upon admission and 50 patients (76.92%) had associated injury with an average Injury Severity Score of 25. Sixty-one cases (93.84%) were operated within 12 hours from admission. Two blunt lesions were treated after 18, respectively 24 hours and two cases presented after 5 respectively 12 years from the trauma episode. Intraoperatively 16 right lesions (24.61%), 49 left (75.38%) were identified. There were 8 deaths (12.30%) and 17 patients (26.15%) developed complications. Hemorrhagic shock upon admission, Injury Severity Score, mechanism of the injury and age strongly influenced the outcome ($p<0.05$).

Conclusions: In emergency trauma settings the diagnostic for diaphragmatic injuries is mainly established by laparotomy. A high index of suspicion and a thorough examination of both diaphragms during laparotomy is mandatory in order to avoid missing traumatic diaphragmatic injuries.

MANAGEMENT OF MASS CAUSALITY INCIDENT IN ROMANIA

Teusdea CB, Toma M, Dogaru S, Popa Luminiţa Mariana, Negoiţă DD

Romania is a Central European country, which has a various relief and it can be affected by many hazards. Hazards can be classified in natural and technological hazards.

In this context the healthcare system in Romania has two parts: civil and military which are providing the medical assistance in our country in every situation. The assessment and the coordination of an emergency situation are realized by National System for Emergency Situation and his components.

The system is activated by any person who calls 112 – “the unique number for emergencies”, where a trained dispatcher assesses the emergency: type, type of hazard involved, location, number of victims, status of the victims and the need for help. The dispatcher from 112 Center/ Integrated Emergency Dispatch Center alerts the qualified first responder team – an ambulance for first aid from SMURD (Emergency Mobile Resuscitation and Extrication Service) or from the Ambulance Service which goes to the incident/accident site. If the dispatcher has information’s that is a Mass Casualty Incident (MCI)/disaster he alerts the coordinator (medical doctor from a Regional Hospital - Emergency Department) and also the Chief Inspector for Emergency Situation from Regional Inspectorate for Emergency Situation. The Chief Inspector announces the Prefect which declares active the Red Intervention Plan for prehospital activities and the White Plan for in-hospital activities. At the MCI site goes also the Police intervention team and a team from the Fire Department.

THE ENCOUNTER OF ASYMMETRIC WARFARE INVOLVES ADDITIONAL SUPPORT TO THE EMERGENCY NATIONAL HEALTH SYSTEMS

Karellas Ioannis, Daliakopoylos Stavros, Houliaras Eleutherios, Sourlas Sotirios, Arsenoglou Athanasios, Liapis Georgios

Purpose: Asymmetric warfare, bypassing armed forces, can cause mass casualties mainly civilians. Depending on the scale of the event, timely medical support can be demanding. This study is investigating the potential of National Health Systems to respond promptly to such a challenge and the readiness of Armed Forces to contribute, minimizing the time that proper medical help is provided to the site of incident, on the ground that the frequency of such incidents in large cities is increasing and that proper medical care on site is lifesaving.

Material and methods: At a 4000000 people city, we investigated how medical emergencies are managed. We interviewed the paramedics and recorded the patients that daily and yearly, emergently requested medical support. We acknowledged the patients that were properly evacuated. The readiness of Armed Forces to support National Medical Services in a mass casualty’s situation was examined.

Results: In a year, almost 240000 patients emergently request medical help. From those, 40000 (16%) choose own ways to access medical care. Anytime, 30-60 ambulances are on the move and yearly, respond to 200000 medical requests, performing 160000 emergency evacuations. Additionally, they perform 50000 scheduled medical evacuations. Great work burden and lack of psychological support the main complains of employed paramedics. Armed Forces use a significant number of ambulances but not specially trained paramedics.

Conclusion: National Emergency Health Systems manage to meet the emergency demands in peace time. Mass casualties can also follow asymmetric warfare. It would be expected, the additional support needed in such occasion, to come from the potential of Armed Forces.

THE MANAGEMENT OF THE MAJOR BURNT PACIENT WITH ASSOCIATED AIRWAY INJURY IN THE CLINICAL CONTEXT OF MULTIPLE CASUALTIES INCIDENT: CASE PRESENTATION – EXPERIENCE ACQUIRED

Marinescu B., Marinescu Penelopia, Ioana Tuhar, Benga Andreea, Popescu F., Oprea T

Purpose: The objective of this study is to present the outcomes of the correct management of the burned pacient, and to share the experience acquired secondary to this event.

Methods: The case sample included 12 patients from the same multiple casualties' incident, with the severity of the burn lesions varying between gr IIb-III and between 5-50% body surface, mainly affecting the upper half of the body (thorax, upper limbs, head and neck). As a common determinant all the cases presented respiratory tract lesions due to the nature of the event-fire in inclosed space followed by toxic fumes inahalation.

The surgical team involved was able to ensure in less than 10 hours the emergency surgical primary care for all of the 12 patients admitted.

Discussion: The distinctiveness of the presented cases consists in the great number of patients simultaneously admitted and treated.

Results: We can report a 100 % survivability, at 50 days all pacients being discharged only with minor granulating areas left to heal spontaneously under local treatment. Most of the studies that we have found and we could reffer to, on the matter of proper airway burn injuries and toxic fume inhalation did not statistically differ from our outcomes, even compared with consecrated burn centres from Western Europe.

Conclusions: The good overall results can be related to the interdisciplinary approach, right from the admission of the patients. Our hospital is a level I medico-military unit, concieved from the beginning to provide emergency medical assistance for the most complex cases.

OP session 2 – Neurology and toxicology

COULD ERYTHROPOIETIN BE USED AS A GOLD STANDARD NEUROPROTECTIVE AGENT IN PATIENTS WITH SEVERE CLOSED BRAIN INJURY?

Stavros Gourgiotis, Stavros Aloizos, Georgios Veloudis, Evangelos Falidas, Constantinos Villias

Aim: Our research was focused on the neuroprotective function of erythropoietin (Epo) in patients with severe closed traumatic brain injury (TBI).

Material - Methods: Our model examined the influence of the outcome and neurological recovery in 42 adults with TBI who were admitted to ICU within 6hrs of their injury and were recruited into a randomized controlled study of two groups; only the patients of the intervention group received 10,000 i.u. of Epo for 7 consecutive days. Prognostic model based on CRASH II injury model and outcome was measured by survival and Glasgow Outcome Scale-Extended version (GOS-E) score at 6 months post-injury.

Results: Six patients (18.7%) died during the first two weeks; 4 of the control group and 2 of the intervention group. A mortality rate of 22.2% and 8.3% for the control and intervention group respectively was observed. A lower rate of good outcome (GOS-E score >4) at 6 months was mentioned among patients of the control group.

Conclusions: The study provides evidence of lower mortality and better neurological outcome for the patients who received Epo increasing the possibility that Epo therapy could be used in clinical practice, limiting neuronal damage induced by TBI.

VALIDATION OF HIPPOCAMPAL VOLUMETRY USING 3-D MAGNETIC RESONANCE IMAGING ACQUISITION IN MULTIPLE SCLEROSIS PATIENTS

V. Petrova, K. Genov, M. Penkov

Introduction: Different Magnetic Resonance (MR) imaging methods have been used to investigate and follow the pathological changes in central nervous system and their evolution in multiple sclerosis (MS) patients. Measuring tissue loss (brain atrophy) is considered a global marker of the adverse outcome of the disease. Hippocampus is a structure critical for cognition. It is sensitive to inflammation. Hippocampal atrophy is detected early in the disease course. MR determination of hippocampal volume (HV) could be useful tool in evaluating correlation between neurodegeneration and cognitive impairment in MS.

Purpose: Validation of hippocampal volumes measured using 3-D acquisition in a PERP protocol.

Methods: MR imaging was performed on a 1.5-T unit. We got 3-D volumetric acquisitions of hippocampus for each subject in a plane perpendicular to the axis of hippocampal formation (PERP protocol). 10 healthy subjects were studied. The results were compared with data obtained from hippocampal volume determination in 10 relapsing-remitting multiple sclerosis patients (RRMS). Both groups were age matched (20-40 years).

Results: For the control group (right hippocampus) the mean hippocampal volume was 9.46 cm (standart deviation 0.98). For the RRMS group was registered mean HV of 8.16cm (standart deviation 0.54). The difference of the mean volume is statistically significant (P =0.003) between two groups. The correlation with age was not significant in both groups (considering the small number of subjects).

Conclusion: Brain volume acquisition provides a measure of axonal loss. Atrophy is a sensitive and reliable marker in evaluating the neurodegenerative process in multiple sclerosis. Hippocampal biometry, in particular, could be applied in estimating data obtained from nonconventional MR techniques like magnetic resonance spectroscopy.

NEUROLOGICAL AND NEUROMUSCULAR SYMPTOMS CAUSED BY WEST NILE VIRUS INFECTION

Diana M. Popescu, Viorel Ordeanu, Marius Necsulescu, Alexandru Filip Vladimirescu, Simona N. Bicheru, Lucia E. Ionescu, Gabriela V. Dumitrescu

West Nile virus (WNV), isolated first from the blood of a febrile woman in the West Nile district of Uganda in 1937, was then identified and re-isolated from sick people, birds and mosquitoes in Egypt (since 1950). The virus have been classified in the genus Flavivirus, family Flaviviridae and since 1999 its geographical distribution include in addition to Africa: Europe, South Asia, Middle East and U.S.A.

The Encephalitic flaviviruses, including WNV, usually crosses the blood-brain barrier and probably they have the ability to multiply in the vascular endothelium.

The clinical manifestations of West Nile fever are medium to severe, occurring after 2-15 days (average 1-6 days) of incubation. Most human infections are clinically inapparent.

About 1 in 150 infected people, presents severe illness. The most important risk factor for neurological damage is age. People over 50 years have a higher risk of developing neurological symptoms. The most common neurological manifestations are: meningitis, meningo-encephalitis and encephalitis.

During the epidemics in the US from 2002 to 2003 neuromuscular manifestations (severe muscle weakness) were recognized as the main causes that have led to increased morbidity and mortality.

Although the potential for contamination, infection and invasion of neurotropic viruses is very high, infections and illnesses of central nervous system are rare. This is explained by the functioning of the host defense mechanisms.

IS THERE A CORRELATION BETWEEN HAND PREFERENCE AND VERTEBRAL - SUBCLAVIAN ARTERY DIAMETER AND VERTEBRAL ARTERY VOLUME FLOW?

Karaman Bulent, Hamcan Salih, Abduramani Asaf, Tasar Mustafa

Introduction: Systemic mastocytosis, often termed systemic OBJECTIVE: During cerebral angiography of cerebral vascular structures it may be necessary to predict the dominant vertebral artery side. The reason of the right and left vertebral artery diameter asymmetry is not clear. We think that there may be a correlation with hand preference and vertebral artery dominance and subclavian artery diameter. In this article we aimed to present a study that investigates correlation between hand preference and vertebral-subclavian artery diameter and vertebral artery flow.

MATERIAL AND METHOD: A total 112 patient were included to the study. We examined fourteen left handed and 98 right handed individuals. The measurements were done with 7.5 MHz linear probe between the fifth and sixth cervical vertebrae at each side. Vertebral artery diameter and volume flow and subclavian artery diameter was measured by two different radiologist and average values were taken.

RESULTS: There were no significant difference in diameter and volume flow of right and left VA between right and left handed individuals ($p<0.05$). Beside this, any significant difference was found in diameter of both subclavian artery between right and left handed individual ($p=0.042$).

CONCLUSION: We found no correlation between differences in vertebral artery diameter and hand preference. Beside that there was no correlation between differences in right and left vertebral artery volume flow and hand preference either. We also found any correlation between both subclavian artery and hand dominance. New and comprehensive researches are needed for the reason and mechanism of vertebral artery diameter asymmetry.

METHOD FOR STUDY THE ELIMINATION ALUMINIUM TO PATIENTS WITH CHORONIC KIDNEY DISEASE

Caragea G., Tudosie M.T., Ştefani C., Forje M., Ardelean L., Bărcănescu S., Ionică M

Alluminium is a toxic microelement. Some toxicity can be traced to deposition in bone and the central nervous system. The toxicity is particularly increased in patients with reduced renal function. In patients with chronic renal disease, the trace elements are removed only during the dialysis procedure. For the determination of alluminium concentrations, a Varian graphite furnace – atomic absorption spectrometer (GF-AAS) was used. We have performed a comparative study concerning alluminium concentrations in blood, determined on subjects in a control group, versus blood alluminium concentrations in subjects belonging to a group of patients undergoing dialysis procedure. Average concentrations of aluminum in the blood of patients with chronic kidney disease, before and after the dialysis procedure is not significantly different statistically, but it is different for subjects with normal renal function. In order to emphasize the dynamic removal of the aluminum in the dialysate during the dialysis procedure, six samples were taken from the dialysis time: zero, 30 minutes, 1, 2, 3 and 4 hours. These values were interpolated using a polynomial Lagrange method. By integrating this equation, one can calculate the amount of aluminum removed during dialysis procedure or can appreciate the amount that could be eliminated if it increased during the dialysis procedure. The average amount of alluminium removed by dialysis procedure is about 5 times higher than the amount removed in 24 h by the patients with normal renal function. GF-AAS method is sensitive, reproducible and has a relatively low cost.

CURRENT DRUG RECIPES EVOLUTION

Forje M., Tudosie M.T., Ştefani C., Caragea G., Ionică M.

Drug recipes suffered an increasing evolution from heroin-carbamazepine mixtures and traditional abuse substances to new “psychotomimetics” with complex structure including ingredients with different functions as: psychotropes, addiction accelerators, nonspecific cholinesterase inhibitors, synthetic drug design LSD, LSA and synthetic cannabinoids. Despite restrictive policies, these products are still commercialized with other uses and benefits, apparently harmless, such as: traditional and medicinal plants, plant fertilizer, bath salts. Consumption of this association can result in very severe clinical symptoms that can be in some cases fatal.

The FPIA and GC-MS techniques highlighted the presence of opiates, antipsychotics, anticonvulsivants, benzodiazepines, and antidepressants of different generations, phencyclidines, cocaine, amphetamines, methamphetamines and LSD-like structures completing the formula of these “recreational” drugs. Because many of assayed compounds lack monoclonal antibodies and also mass spectra required for identification for the new drug design compounds it is necessary to continuously improve methods and techniques in extraction, detection, quantification and assay of biological samples.

The authors present a FPIA and GC-MS method to be used in the identification of psychotomimetic mixtures and special condition liquid-liquid extraction for LSD-like structures to be used in GC-MS method.

The urine samples have been collected from the patients presented in the ER and other similar medical facilities in Bucharest and have been analyzed on a FPIA-COBAS Integra 400 Plus and also on a GC-MS Saturn 2000 Varian. PMW, NIST, Wiley libraries were used for identification.

A CASE OF ACUTE VOLUNTARY INTOXICATION WITH INSECTICIDES CHOLINESTERASE INHIBITORY

Dumitraşcu M., Macovei R.A., Dănescu I., Tudosie M.T., Caragea G, Forje M., Ionică M.

In the Clinical Emergency Hospital Bucharest, cases of poisoning are frequent cholinesterase inhibitor compounds, representing a challenge for physicians in the therapeutic conduct. The use of these compounds widely in agriculture and households, leads to an increased number of accidental poisonings. At the same time, it remains a method used quite frequently suicidal purposes. Always laboratory tests guides physicians regarding treatment. Therefore, the development of toxicology lab was a priority. These compounds are quickly metabolized in the body, causing either laboratory compound itself, but more often, its metabolites. The method is the determination of the compounds and/or their metabolites is gas chromatography coupled with mass spectrometry (GC-MS). The clinical picture includes symptoms of associated diseases, the most important remains rapid determination of compound that produced intoxication, thus leading doctor right treatment.

The paper presents a case of voluntary intoxication with a mixture of insecticide widely used: cyfluthrin, transfluthrin, prallethrin, propoxur and chlorpyrifos, an old patient with cardiac and neurological pathology associated. Existing flaws could mislead the physician in the diagnosis, the patient is comatose, found by neighbors in the house, without being able to perform a history too broad. Cardiac and neurological symptoms could mask toxidrom cholinergic if some signs would not be determined doctor, who examined the patient, to recommend a toxicological analysis, which was done quickly and confirmed the suspicion of acute poisoning with cholinesterase inhibitors. Treatment was symptomatic management reactivated without cholinesterase, as in this case, they can produce serious neurological side effects.

ADMINISTRATION OF VITAMIN K IN PATIENTS WITH OVERDOSE OF ORAL ANTICOAGULANTS

Truţă E., Ştefani C., Tudosie M.T., Constantin L., Stoica A., Caragea G., Forje M., Ionică M

The relation between the anticoagulants and body´s ability to control homeostasis is complicated. Doses that are too law may prevent clots, while doses that are too high may cause severe bleeding. In order to obtain a clinical efficacy and limit the risk of either bleeding or clothing vitamin K antagonists require rigurous and continuous adjustment of INR (international normalized ratio). Vitamin K is mainly indicated as an antidote against hypoprohrombinemia due to excesive coumarin anticoagulation. Our aim was to assess if vitamin K is being used acording to the available clinical evidence, estimating the impact of unnecesary prescriptions. We included 40 oral anticoagulants prescription written during 2015 year. The patients handed their treatment on their own (100%) and took an average 5.5 different drugs a day. All patients had increased INR. The main reasons for increased INR were: neglect monitoring INR; did not meet the doses indicated by the doctor (10); were not able to travel for collection of biological samples (3); voluntary ingested (2); mistook drugs (2); overdose history (2), possible drug interactions (10). Lenght of hospitalization was between 2 - 19 days. Vitamin K used as an antidote was not required, 5 patients, or doses administered were not recommended by the literature, 20 patients. It is one of the medical staff´s responsability to make sure that the patients have a good understanding of their treatment and it´s monitoring.

OP session 3 – General surgery

DAY SURGERY DEVELOPMENT AND PRACTICE: KEY FACTORS FOR A SUCCESSFUL PATHWAY

Rasvan Hristea, Cristian Dragos Stefanescu

To understand history is to begin to understand the future. This paper explores the beginnings of modern day surgery and via its growth and advantages looks at how it can develop in the future. The advantages of day surgery are clear and well documented. But, as in the past, barriers exist to its expansion and these are examined. The reasons for this include medical conservatism and protectionism. However, in the longer term there is no doubt that no country, rich or poor, will be able to resist a move to day surgery because of the economic benefits combined with quality treatment that accrues from this approach. In the not too distant future, the question will not be 'Can this patient be treated on a day basis?' but 'Why cannot this patient be treated as a day case?' Day surgery rather than inpatient surgery will become the norm for elective surgery.

ANESTHESIA FOR DAY SURGERY

Teodora Serban, Simona Butoi, Rasvan Hristea, Cristian Dragos Stefanescu

As with all cases of surgery, the choice of a proper anaesthetic drug and technique for day surgery should be based on considerations of safety, quality and cost effectiveness, with the safety issue as the most important concern. As day surgery has some specific characteristics, the way of looking at these three main issues may be different from major inpatient surgery. Day surgery should be well planned, elective surgery done during daytime, usually of minor or intermediate invasiveness and involving stable patients of good or fairly good general health. This implies that the risk of severe problems arising from patient safety is less likely to occur. On the other hand, if problems do occur they will be much less tolerated and accepted by patients and society. The discussion on the ideal choice of anaesthetic technique should be based on demands for a close to zero risk of mortality and permanent disability, and then moving the focus into aspects of quality and cost efficacy. Further, the success of a chosen anaesthetic is highly dependent upon adjuvant issues, such as the skill and routines of the personnel involved, proper monitoring and dosing, and the use of non-anaesthetic adjuvant drugs and methods for pain and nausea protection.

SLEEP SURGERY IN ONE DAY IN ONE PLACE

Cristian Dragos Stefanescu, Cristina Stefanescu, Teodora Serban

INTRODUCTION. The appropriate level of postoperative monitoring for most patients undergoing surgery for obstructive sleep apnea (OSA) remains controversial. Our objective was to document the postoperative course of patients undergoing OSA surgery.

MATERIALS AND METHODS. Study Design: Prospective cohort study. All patients were evaluated (polisomnography included) at the somnology department of The National Institute of Aerospace Medicine and undergoing „on demand" to surgery for OSA at our day surgery center, from 2009 to 2012. Outcome measures were: 1) incidence of respiratory complications requiring nursing intervention, 2) level of postoperative blood oxygen saturation divided into three groups: mean oxygen saturation in recovery room, mean oxygen saturation in step-up unit and lowest oxygen saturation over the 24 hour period.

RESULTS. The overall incidence of nursing intervention in response to a respiratory complication was less than expected. Mean SpO_2 was above 90%.

CONCLUSIONS. In selected patients undergoing to planed and minimally invasive surgery for OSA routine ICU (intensive care unit) postoperative monitoring is not mandatory.

MINIMALLY INVASIVE vs OPEN GASTRIC CANCER RESECTIONS

Kyosev Vasil, Kotashev Georgi, Mutafchiyski Vencislav, Vasilev Krasimir, Ivanov Plamen, Grigorov Grigor, Hristova Vasilena, Popivanov Georgi, Petrov Hristo

Aim: Minimally invasive surgery of gastric cancer has emerged as a result of the technical advances, better understanding of gastric physiology, and more knowledge of the biologic behavior of gastric cancer. The aim of this study was to present our experience with minimally invasive radical resection for distal localize gastric tumors, to compare with open gastric resections, to evaluate the surgical outcomes and oncologic efficacy of minimally invasive approach.

Material and Methods: This study included 20 patients: eight (40%) underwent minimally invasive subtotal gastrectomy (MG), while twelve (60%) patients open subtotal gastrectomy (OG). The following variables were evaluated: age, sex, comorbid conditions, tumor size, and histological type, depth of wall invasion, and presence or absence of lymph node metastasis. The surgical variables investigated included operating time, blood loss, postoperative complications, and length of postoperative stay.

Results: The demographics, preoperative data, and characteristics of the tumor were similar. Median operative time for the minimally invasive approach was 258 min (range 150-385 min) compared with median of 136 min (range 85-205 min) in the open group (p < 0.01). Minimally invasive surgery resulted in less intraoperative blood loss compared with OG. All resected margins in two groups were free of tumor invasion. The mean number of resected lymph nodes was 31.6 ± 14.4 in the OG group and 28.0 ± 11.9 in the MG (P = not significant). MG-patients had an earlier return to normal bowel function and length of hospital stay was 6 days (range 4-14 days), compared with 8 days (range 6-19 days) in the open group (p = 0.01).

Conclusions: This study demonstrated that minimally invasive subtotal resection for gastric cancer had good result and were feasible and safe procedure. Minimally invasive approach can obtain adequate margins, follow oncologic principles and is an excellent alternative to the more traditional open approach.

THE IMPORTANCE OF BARIATRIC SURGERY IN ARMY FORCES – PRESENTATION OF OUR PRELIMINARY RESULTS

Tasis Nikolaos, Sotiropoulos Georgios, Barkolias Christos, Fradelos Aggelos, Barbalia Ioanna, Panagakis Georgios, Terzis Ioannis, Xanthopoulou Georgia, Georgopoulos Nikolaos

Aim: Aim of our study is to highlight the effect of bariatric surgery in improving quality of life and working efficacy of obese personnel.

Material – Method: Our department contacted a retrospective study, collecting data from 41 patients who underwent bariatric surgery in our hospital between February 2009 and November 2014. Patients were asked to fill a questionnaire collecting their demographic data and calculating their BMI before surgery, at its lowest point and at present time. Furthermore, the patients were asked to evaluate their changes in quality of life and working efficacy after surgery in a scale from 1 to 10, with 5 indicating stability, 10 maximum improvement and 1 maximum aggravation.

Results: Thirty eight patients completed our questionnaire. Five, of them, underwent gastric bypass surgery and thirty three, of them, laparoscopic sleeve gastrectomy. The average body mass index before the procedure was 45.99. The average body mass index after the procedure was 33.67. The average lowest body mass index after the procedure was 31.59. Mean evaluation of their working efficacy after surgery was 8.26. Mean evaluation of their quality of life after surgery was 8.31.

Conclusions: Significant improvement was recorded in both working efficacy and quality of life. Patients productiveness was increased, their working environment improved, as well as, their social life. Further data is collected by our department, at the moment, for future more detailed reports on this subject.

BARIATRIC SURGERY: TWO YEAR OF PRACTICE IN OUR CENTER

Diana Toma, Serban Vasile, Mircea Lica, Rely Manolescu, Paula Neicutescu

Introduction: Bariatric surgery is the most effective therapy available for morbid obesity and can result in improvement or complete resolution of obesity comorbidities.

The morbid obese patient have a diversity of clinical and occult obesity-related comorbidities that necessitates a multidisciplinary team approach in the preoperative evaluation - cardiac, pulmonary, psychiatric, and endocrine.

Laparoscopic sleeve gastrectomy (LSG), it’s a procedure that reduce the dimensions of the stomach to about 15-20% of its original size by removing of a large portion of it, following the greater curve.

We present our results after two years of constant practice of LSG in morbid obese patients in Medlife - Life Memorial Hospital.

Matherial and method: In our bariatric center, 82 patients with obesity, underwent to laparoscopic sleeve gastrectomy, between 2014 – 2015. Body Mass Index (BMI) at admission ranged from 32 to 53 (mean 42) and most of the patients were women (86 %). 39 patients (47 %) presented associated comorbidities – hypertension, diabetes mellitus, sleep apnea syndrome. Laparoscopic sleeve gastrectomy was performed in all patients; conversion rate was null.

Results: No major complication (leakage or active bleeding) was encountered. Readmision rate was 4.8 % (4 patients) mostly for postoperative nausea and vomiting. One year scheduled control from the beginning of the programme encoutered excess weight loss percentage (% EWL) of 68.4 %.

Conclusions: Bariatric surgery gained a major role in the treatment of severe and morbid obesity. Low complications rates and weight loss above 50% entitle us to consider that sleeve gastrectomy is a safe and effective method of treatment in severe and morbid obesity.

OUR FIVE YEARS EXPERIENCE IN SLEEVE GASTRECTOMY ON MILITARY PERSONNEL – OUR PRELIMINARY RESULTS

Barkolias Christos, Sotiropoulos Georgios, Tasis Nikolaos, Fradelos Aggelos, Panagakis Georgios, Barbalia Ioanna, Terzis Ioannis, Xanthopoulou Georgia, Georgopoulos Nikolaos

Aim: Aim of our study is to assess the long term results of laparoscopic sleeve gantrectomy regarding BMI reduction and patient satisfaction.

Material – Method: Our department landed a retrospective study, including 34 patients who underwent laparoscopic sleeve gastrectomy in our hospital between 2009 and 2014. Patients were divided in 3 groups. The first consisted of those who received surgery in 2014 (group A), the second of those who received surgery in 2013 (group B) and the third from patients who were subjected to surgery between 2009 and 2012 (Group C). Demographic and somatometric data was collected in order to calculate BMI score before surgery, at the lowest point after surgery and at present time. Satisfaction of patients from the surgical results was evaluated in a scale of 1 to 10, 5 indicating neutrality, 10 maximum satisfaction and 1 maximum dissatisfaction.

Results: Both groups A and B achieved similar maximum BMI reduction (32% and 34% respectively) and managed to maintain a steady BMI until today. Group C reached a similar maximum BMI reduction (33%), but it presented a partial relapse, as it now presents a 26% BMI reduction compared to its original BMI. Satisfaction remains high in all groups.

Conclusions: Our preliminary results indicate the promising role of laparoscopic sleeve gastrectomy in treating obese personnel. The partial relapse of group C might urge the need for choosing gastric bypass as treatment for selected patients. Further data is collected by our department for more conclusive results.

CYSTIC DUCT REMNANT CALCULUS AS A CAUSE OF POST-CHOLECYSTECTOMY SYNDROM: CASE REPORT

Atanaskovic Aleksandar, Kostic Zoran, Neskovic Branimir

AIM: There are several causes of post-cholecystectomy syndrome (PCS), and the presence of stones within cystic duct remnant is one of them, with estimated incidence <2.5%. The objective of this work is to emphasize cystic duct remnant calculi as potential cause of PCS, its diagnostics and treatment.
